Abstract

Lots of works have been conducted to explore and explain inter-organizational relations between supply chain partners. However, we have noticed that there is no accurate agreement between authors. Thus, to better understand this disparity, we studied supply chain inter-organizational relationship dynamics in eight (8) different industries to bring out an analytical framework that allows a better understanding of such an issue. These case-studies instruct professionals and researchers so that they bring up their level of abstraction that remains appropriate to catch this dynamics in order to guide decision making and future research and studies.

Key words: Inter-Organizational Relationships, Supply Chain Dynamics, Social Exchange Theory,

1: INTRODUCTION

To claim a relative adequacy between supply and demand, it is necessary to adopt a forward-thinking of integration of relevant generating value processes and activities among all players in the supply chain (Lambert and Cooper, 2000), while maintaining agility, adaptability and alignment between their different interests (Lee et al., 2000). In this way, supply chain can be defined as a hierarchical, dynamic and process oriented network, consisting of a set of autonomous companies (from the first supplier to the end customer), linked by upstream and downstream flows (physical, informational, financial and knowledge) and driven by different

level relationships, established in order to satisfy customers through better coordination and integration, but also by means of greater flexibility and responsiveness. These supply chains can be presented as unavoidable phenomena arising from a need for coordination and flexibility among a set of companies. In this sense, supply chains exist, whether managed or not (Mentzer et al. 2001).

We have noticed that a field called behavioral operations management (Chen et al., 2012), or we can also call it behavioral supply chain management, is about to be distinguished in new trends. Basically, two main aspects characterize management and decisions in supply chains. The first one is *technical-oriented aspect*, which include mainly engineering, economic and financial domains, namely those that use majorly a rational objective reasoning to solve emergent issues and inquiries. The second one is social-oriented aspect that includes essentially social and psychological domains, otherwise those that, in addition to rational thinking, include subjective cognition when exchanging with others. For the latter, Klassen and Vereecke (2012) stress that supply chain management has left social concerns last. They add the fact that lots of pioneering companies find difficulties to define, understand and plan for social issues. Accordingly, we have noticed that one of the main factors that drive companies to marginalize management of social aspects of relations with their supply chain partners, in a structured and justified manner, is the struggle to assume relevant inter-organizational relational variables and the dynamics governing them.

This issue is even more important that the partners of a supply chain are still evolving using bipolar strategies, including cooperation and competition (Zouaghi et al., 2010). Even more, in a supply chain positioning, both cooperation and competition are essential, because they coexist in an ago-antagonistic systemic way (Zouaghi and Spalanzani, 2011). Moreover, the fact that the supply chain embodies a dynamic network, made it more exposed to variations and instabilities giving rise to conflicts or opportunistic behaviors, because of the uncertainty and ambiguity of particular situations. But unexpectedly, some altruistic behavior can emerge from some partners aiming at quite subjective goals. In this sense, the Social Exchange Theory (SET) can better elucidate this phenomenon.

So in this paper, we are going first to overview social exchange theory. This will allow us to better introduce our concepts to come up with a framework that elucidate supply chain relational dynamics within this paradigm. Then, we present our methodology, namely a multiple-case methodology including cases selection and data collection protocol. Next, we

will present our results with a discussion, and finally we conclude and give further research trends.

2: SOCIAL EXCHANGE THEORY OVERVIEW

Initiated by authors like Blau (1964), the Social Exchange Theory (SET) represents a theoretical corpus which argues that individuals or organizations are in a social exchange logic looking for rewards and benefits, and avoiding punishment Emerson (1976). In this way, companies establish relationships with others to warrant mutual advantages. Thus, in contrast to economic exchange theory, which define an actor as a homo economicus, which is rational egoist, utilitarian and hedonistic, the SET highlight the fact that this actor is also characterized by altruism, social values and even subjectivism. Blau (1964) stipulates that the SET is characterized by indefinite individual engagement and trust such as intrinsic rewards, hence situated between rational calculation of gain and pure affective behavior. Moreover, social exchange theory insists more on insuring long-term social relations, than on a short-term transaction in the marketplace.

Furthermore, in a SET approach, future actions and behaviors are conditioned by former ones. In this sense, the more beneficial is the result of a member's action, the more likely this one is to perform the action again (Blau, 1964). So when a partner does not receive an expected benefice or incurs an unpredicted punishment, will behave negatively in future actions (Homans, 1961). These benefits are not fixed with a rational calculation; they are evaluated compared to a certain number of quantitative and qualitative elements, which generally cannot be easily determined. So it's difficult to evaluate them on a transaction approach basis (Masterson, 2000).

For the SET proponents, power is seen as a significant factor that interferes within a relationship. Power has been defined as the ability of a member to influence or to control the decisions and the behavior of other members (Friedberg, 2009). But, relational attitudes and behaviors are conditioned by the perceived justice established by the more powerful member of the exchange and that the enactment of such policies allows the member to retain and protect its power (Griffith et al., 2006). These elements stimulate the nature of the relationship between members that will guide the future exchange.

3: SUPPLY CHAIN RELATIONAL DYNAMICS: CONCEPTUEL FRAMEWORK

When reviewing the most relevant literature that intervene within a supply chain, what stand out first is the tiered relationship between different actors and their corresponding influence, namely the power they have (Cox, 1999; Benton and Maloni, 2005). The exercise of this power creates an instinctive reaction of the one who undergoes it, resulting in a level of satisfaction (Benton and Maloni, 2005). This level of satisfaction presents, therefore, a second major factor and has a direct impact on the nature of the relationship (conflict, cooperation, coordination, collaboration) between different supply chain actors, which also depends on trust, commitment of actors and interdependencies between their different processes (Mohr and Spekman, 1994; Mentzer et al., 2001). Finally, the relational antecedents determine the degree of information sharing (Patnayakuni et al., 2006), which presents another factor in this relational dynamics. On this basis, these factors will be detailed and analyzed in order to constitute a framework explaining the relationship dynamics that governs the supply chain.

3.1: Power and satisfaction

One of most used definition of power is that of Dahl (1957, p.290). He stipulates that “A has power over B to the extent that he can get B to do something that B would not otherwise do”. Also, cited by Friedberg (2009), Crozier (1970) defines “the power of an actor A as its ability to impose on an actor B terms of trade that are beneficial to him”. So power is a relative force, justified or not, a player can have on another within a given relationship.

For Benton and Maloni (2005), the power plays a decisive role in the supply chain. It allows the determination of relational influences between actors, especially since the identification of its sources shows that it can have a varied effect on inter-organizational relationships but also on the behavior of each actor. Moreover, the power allows the hierarchy of structural dominance, defined by Cox (1999) as situations in which there are one or several dominant players, who are able to capture or control the key resources that generate value. In the same vein, Munson et al. (1999) state that a player has the power in a supply chain if he is in possession of a strong market position, he has access to a major part of financial resources; he has access to important or critical information or he has an irreplaceable position. They add that the exercise of power within the supply chain revolves around price, inventory, operations, channel structure, and information controls.

Moreover, the typology of French and Raven (1959) identifies five sources of power: reward, coercion, legitimacy, reference and expertise. Another source added by Raven (1959), which is information. However, Hunt and Nevin (1974) classify power in coercive and non-coercive

power. Molm (1997) states that this classification is more relevant because the other four sources of power determined by French and Raven (1959) (reward, legitimacy, reference and expertise), considered as non-coercive, include benefits of the promotion of desired behaviors while the coercive power source is mainly based on the exercise of force. Consequently, this latter type will be taken into account in our research, since it is sufficient to distinguish the behaviors in a supply chain. This has been studied before by Beier and Stern (1969) who found that non-coercive power is an alternative that can increase satisfaction for weakest members. Consequently, the latter type will be taken into account in our research, since it is sufficient to distinguish behaviors in the supply chain. Even though, the typology of French and Raven (1959) updated by Raven (1964) may provide some explanation, since it allows to have more information on the sources of power.

The exercise of power by an actor on one or more other players, whatever its source, is not without consequences. In other words, the exercise of power in a coercive logic or not has not the same echo. Thus, the satisfaction of partners presents a major factor in building relationships and making decisions in the supply chain. Anderson and Narus (1990) defined satisfaction as a positive emotional state resulting from the evaluation of all aspects of the relationship between a company and its partner. Through our research, we adopt the definition of Benton and Maloni (2005), which stipulate that partner satisfaction is a feeling of fairness in the relationship whatever existing power imbalance. In this way, the work of Benton and Maloni (2005) shows that the coercive power (reward, coercion and legitimacy) has a negative impact on the satisfaction of the partner who undergoes it. By cons, non-coercive power (reference, expertise and information) has a positive impact on the level of satisfaction of the same partner.

Hunt and Nevin (1974) outlined six main benefits arising from the satisfaction of the partner that undergoes power. When satisfied, this partner has a high level of morale, cooperate better, avoid to deliberately terminating contracts, is less likely to file individual or class action suits against who has the power and is less likely to seek protective legislation. Therefore, partners' satisfaction greatly improves the relationship between them. So we can say that the level of satisfaction has a greater or lesser impact on the nature of the relationship that binds the different actors. In this line, quoted by Benton and Maloni (2005), Guneshan and Harrison (1997) showed that the level of satisfaction represent a significant factor in the performance of long-term relationship. Similarly, Skinner et al. (1992) have demonstrated

that the level of satisfaction has a positive relationship with the cooperation, and a negative relationship with conflict.

3.2: Trust, commitment and interdependence

Trust can be described as a belief that the company would accomplish only actions that will yield positive results (Anderson et Narus, 1990). This trust arises when one party believes in the reliability and the integrity of its exchange partner (Morgan and Hunt, 1994). For Högberg (2002), this trust is gradually developed with the gradual deepening of the relationship through a process of mutual adaptation, although not necessarily in a symmetrical manner, to the needs of the other partner. Likewise, commitment is defined as an implicit or explicit pledge on the continuity of exchange between partners (Dwyer et al., 1987). By relating these concepts Morgan and Hunt (1994), state that a company can expand cooperation by increasing trust and commitment. However, trust has a major influence on the players' commitment in the relationship (Achrol, 1991; Ruyter et al., 2001).

In the same line of Kambil and Short (1994), Kumar and van Dissel (1996) state that the interdependence in the sense of Thompson (1967), determines the level of relations between the different actors. The levels of interdependence, namely pooled interdependence, sequential interdependence and mutual one, as they have been determined by Thompson (1967), have a greater or lesser extent on the level of relations between actors.

3.3: Tolerance and altruism

As we have seen before, SET include in inter-organizational behavior objectivism and subjectivism, but also both opportunism and rigor, and altruism and tolerance. Autry et al., (2008) stipulate that these last behaviors reproduce an effort to help and support supply chain partners facing business issues, or provide them with knowledge that they will assume themselves. These authors add the fact that tolerance presents the willingness to accept inconveniences when performing business with partners, such as a decrease in performance, impositions on the focal firm coming from inevitable externalities, and other inconveniences relative to cooperating with partners. They also underline the fact that inter-organizational tolerance comprises the allowance of such inconveniences without penalty or sentence.

Moreover, Ge and Hu (2012) have studied through game theory, companies' altruistic motivations in supply chains. They demonstrate that supply chain performance relative to altruism remain among situations depending on decentralization and integration. They show besides that a manufacturer, as a leader, should bargain with an egoistic retailer, while a

retailer, as a follower, should deal with a manufacturer with altruistic liability, to ensure performance.

3.4: Inter-organizational relationship nature

Thereby, we can say that within a supply chain, the nature and intensity of the relationship that links the different actors can be approached with a dichotomous logic. Indeed, either the factors that influence this relationship are more or less positive leading to an agreement position, which can result in cooperation, coordination or collaboration. Or, they are relatively hostile, and here companies are facing a situation of conflict and opposition.

In supply chains, conflicts can arise between partners from differences relative to certain elements. Hocker and Wilmot (1985) defined the conflict as a disagreement expressed between at least two interdependent parties who perceive incompatible goals, poor rewards and interference of the other party in achieving their goals (mutual). These conflicts can arise from a difference of power, competition for scarce resources, a tendency to differentiate a negative interdependence between entities, an ambiguity about the legal responsibility or authority, a deterioration of the image of one of them or its value (Deutsch, 1969). Being in conflict, members of a supply chain tend naturally to a local optimization to the detriment of the overall performance of the chain. To address this, members of a supply chain cooperate, coordinate or collaborate in the sense of common interest.

Moreover, supply chain integration depends, among others, of organizational factors such as trust, commitment, interdependence, organizational compatibility, vision, core processes, leadership and support of top management (Mentzer et al., 2001). Thus, we can say that in addition to previously invoked satisfaction level, trust, commitment and interdependence are critical determinants of the relationship nature between different partners (Mohr and Spekman, 1994).

3.5: Information sharing

At the supply chain level, information is critical to coordination and flow optimization. Retention or bad reporting can cause distortion and loss of visibility; and thus amplifying the Bullwhip effect (Lee et al., 1997) and decreasing the supply chain performance. Furthermore, it should be noted that the fact of sharing information between companies has an impact on performance (Lee et al., 2000) depends on a better consideration of the antecedents of this sharing (Samaddar et al., 2006). That said, Patnayakuni et al. (2006), shows that information

sharing is influenced by previous relationships, then the nature of relationships that link the various players in the supply chain.

Through inter-organizational setting, three situations of sharing can be presented, namely a situation where no information is shared, a situation where certain information is shared and a final in which nearly all information is shared (Gavirneni et al., 1999). Moreover, the degree of information sharing also depends on two key elements, namely the information quality and the cost that allows access to it. Zhou and Benton (2007) state that the quality of information shows the degree to which the information exchanged between companies coincides with their needs. The quality of information is determined by its completeness, accuracy (the absence of noise), its reliability, smoothness and accuracy, timeliness, punctuality, its shape and richness, and finally to its accessibility (Reix, 2004). This quality is desired just for the cost that allows its availability. If the cost of information is too high some quality criterion can be set aside. Therefore, before sharing information, members of a supply chain evaluate the quality/cost ratio in a precise or approximate manner. Consequently, this ratio has a direct impact on the degree of information sharing between different supply chain partners.

4: MULTIPLE-CASE STUDY METHODOLOGY: CASES ASSORTMENT AND DATA COLLECTION

Studying and contextualizing complex phenomena, such as inter-organizational relational dynamics between companies within a supply chain, requires an in-depth study methodology. Thus, we opted for a qualitative methodology because, as mentioned by Danzin and Lincoln (2011, p.6), “it uses semiotics, narrative, content, discourse, archival and phonemic analysis”, and in our case, we need to explore all information and knowledge resulting from these kinds of analysis, to go beyond what is really perceived by quantitative studies. Subsequently, we have selected case study methodology or more precisely multiple-case study methodology in order to explore similarities and differences within and between cases, and to capitalize through replicating findings by means of cases. So, it is important that these cases are overflowed carefully so that the researcher can identify analogous results crosswise cases, or contrast results based on existing theory (Yin, 2008). Thus, it should be noted that each case has to be studied separately, but the main interest lies in the collection of these cases or in the issue displayed in these cases (Stake, 2006).

4.1: Cases identification and selection

Case identification and selection is an important step in multiple-case studies in particular. Flyvbjerg (2011) identifies six case selection strategies, and have classified them in two main classes, namely random selection strategies and information-oriented selection strategies. In our work, we adopt the maximum variation cases strategy which represents an information-oriented selection. Flyvbjerg (2011) specifies that this strategy is used to obtain information about the implication of numerous circumstances or settings for case process and outcome. He gives examples of some dimensions like the size, the organization form, location and budget. In our instance, we select our cases depending on six variable dimensions, namely product (simple to complex) and manufacturing system (mass to customized production) characteristics, systemic and environmental uncertainty (deterministic to chaotic), strategic position in economy, and legal and governmental influence. We have selected 8 cases, each one in a specific industry, namely, retail industry, parachemical industry, automotive industry, agri-food industry, sporting goods industry, aerospace industry, toy industry and luxury industry.

4.2: Data collection

As we have mentioned above, one of the characteristics of qualitative methodologies is the fact that we can use plenty of information sources, such as narrative information, discourses reports, archives, internal and external documents, and so on. In this respect, Yin (2008) stipulates that multiple-case study exploits multiple sources of evidence for assessment. Thus, in our research we used information from three major sources, namely internal documents (flow charts, internal notes and reports, ...), external reports (companies websites, consulting and experts reports, ...), and Semi-structured interviews (Supply chain managers, Logistics leaders, ...).

4.2.1: Internal documents and external reports

Depending on companies studied, the diffusivity and the accessibility to their materials, internal documents providing information on their operations, logistics and supply chain system, and others enlightening their activities were exploited to understand their formal functioning. Also, external reports were used to have an outside view on these companies, but also to have more accurate information about their industry structure and their positioning inside. All these documents were also uses to analyze our cases after having done semi-structured interviews.

4.2.2: Semi-structured interviews

To reach our goal which is the understanding of a complex phenomenon, but at the same time staying in specified area of conceptual framework, semi-structured interviews were conducted depending on a pre-determined interview protocol, specifying the main elements covered with an opened part. We chose the semi-structured interviews to provide both *flexibility*, which cannot be allowed by structured interviews, and *focus* which can hardly be guaranteed through an open interview. Interviews were conducted with persons that were the more concerned with our issue. Supply chain, operations and logistics managers and other competent people were interviewed face-to-face or by telephone, in late 2011 and early 2012. These interviews were transcribed and analyzed in terms of our conceptual framework.

5: RESULTS ANALYSIS AND DISCUSSION

To meet scientific expectations and rigor of qualitative researches, and specifically multiple-case studies, we explore correspondences and differences within and between our 8 cases, to build knowledge by replicating results. By referring to Table1 and Table2, we can see first that relational characteristics differ depending on the industry. In most of supply chains studied, power is non-coercive, and is in most of industries (4/8) expert and/or legitimate. So, in the retail industry, automotive industry, agri-food industry and toy industry, power is mostly based on the *expertise and capabilities* of the focal company or on its *legitimacy*. We have also noticed that power can be *leveraged from the Group* to which belongs the focal company, as in aerospace industry, or can be based to *availability or access to raw materials*, as for luxury industry. Likewise, we can notice that power of the focal companies can be based on *market oriented sources*, such as for sporting industry in which we have found that power is based mostly on the *percentage of market share*. We can see for some power sources that Munson et al. (1999) has mentioned some of the power sources in a supply chain, which are the possession of a strong market position, and access to a major part of financial resources.

When analyzing satisfaction, we can advance the fact that there is *satisfaction for an input* like *developing capabilities and knowledge* in aerospace, automotive and parachemical industries, or *satisfaction for an output* like *volume orders* in toy industry, or *referencing* in the retail industry. Analytically, we can say that the angle chosen in the literature, cf. Benton and Maloni (2005), to consider satisfaction the fact that power is coercive or not, can mislead

us because we found in our study that a partner can be satisfied even if power of the focal company is coercive. Therefore, we think that approaching satisfaction is better fecund when dealing with its stance (input or output).

Examination of our cases allows us to see that trust and commitment are interdependent concepts, and that commitment aspect follows generally trust facts. For most supply chains, trust is cognitive and based on several elements. For example, in automotive, aerospace, sporting and toy industries, trust is based on *competencies, innovation and research capabilities* of partners. In agri-food and luxury industries, it depends mostly on *network and partnership period*. In retail industry it depends on the *share of the partner in the turn over*, and in sporting industry, in addition to competencies, it depends on the *brand of the partner*. For commitment, most of industries move towards *SLAs, openness to auditing* or simple *performance objectives*.

Dependence and interdependence between supply chain partners is seen as contingent to the *number of partner* determination, as in retail industry; or, *to market complexity and competition level*, as in parachemical industry; or, to technological concerns like in automotive and aerospace industries; or else to *product availability*, like in agri-food; or on *brand specificity and exclusiveness of a partner*. We can also notice that dependence can be due to *material investments and idiosyncrasy of products*.

For tolerance and altruism, it seems that most of supply chains focal companies' presents and altruistic behavior and a high level of tolerance regarding small *size of partners*. We have noticed it in all retail, automotive, aerospace and agri-food industries. For supply chains in other industries, such as parachemical and aerospace, tolerance and altruism are *problem dependent* (frequency and intensity). So if the problem is not frequent and its impact is not important, the focal company will be tolerant and altruistic in helping its partner to overcome the problem. Also, when it comes to assisting suppliers for *growth and enlarging variety of product* proposed, for respectively sport industry and toy industry, companies tend to be more tolerant and altruistic.

When analyzing inter-organizational nature, we have noticed that in most of supply chains, this nature *depends on flow management strategy of the focal company*. For example, in retail, parachemical, automotive, aerospace and sporting industries where lean and synchronous flow management strategies are adopted, focal companies are developing close collaborations with partners, and they *manage conflicts through movements, negotiation and*

financial penalties. For Agri-food industry, this nature *depends on the structure of the focal company*. In this case, it concerns a cooperative, so a lot of small companies cooperate depending on this structure. Finally, analysis of information sharing through cases shows that most of information shared between supply chain partners concern *operations, control and performance*. We have also noticed that most supply chain partners use *EDI, ERP and WMS* systems and *extranets* in the supply chain context. All this can be consolidated in Table3.

Table3: Majors factors influencing supply chain relational dynamics

Major factors	
Power	<ul style="list-style-type: none"> Expertise and capabilities Leveraged from the Group Availability or access to raw materials Percentage of market share
Satisfaction	<ul style="list-style-type: none"> Satisfaction for an input like developing capabilities and knowledge Satisfaction for an output like volume orders in toy industry or referencing
Trust	<ul style="list-style-type: none"> Competencies, innovation and research capabilities Network and partnership period. Share of the partner in the turn over, Brand of the partner
Commitment	<ul style="list-style-type: none"> SLAs Openness to auditing Performance objectives
(Inter)dependence	<ul style="list-style-type: none"> Number of partner Market complexity and competition level Product availability Brand specificity Exclusiveness of a partner Material investments and idiosyncrasy of products
Tolerance and altruism	<ul style="list-style-type: none"> Size of partners problem dependent (frequency and intensity) growth and enlarging variety of product proposed
Inter-organizational relationship nature	<ul style="list-style-type: none"> depends on flow management strategy of the focal company manage conflicts through movements, negotiation and financial penalties Structure of the focal company
Information sharing	<ul style="list-style-type: none"> Operations, control and performance. EDI, ERP and WMS systems and extranets

Table1: Relational characteristics in retail, parachemical, automotive and aerospace industries.

	Case 1: Retail	Case 2: Parachemical	Case 3: Automotive	Case 4: Aerospace
Power and satisfaction	Power based on mastering of transport solutions and goods distribution and suppliers referencing.	Coercive power. Satisfaction assessed through 13 criterions including 4 aspects: purchasing, quality, supply chain and technology)	Expert and legitimate power. Importance of satisfaction for advancement and development concerns (co-engineering)	Power leveraged from the Group. Capability and knowledge based satisfaction.
Trust and commitment	Depends principally on the share of a partner in the turnover.	Mutual trust and SLA ¹ for commitment	Cognitive trust is based on competencies. It depends also on countries and importers characteristics. Commit through SLA (quality, environmental, ...)	Trust based mostly on closeness to government and army, and also on innovation and research capacity. Openness to a regular audit.
(Inter)dependence	One supplier per product and one supplier of aid.	Interdependence due to hyper competitive market and context	Depends mostly on technological concerns. Interdependent with OEMs ² and dependence of subcontractors.	Suppliers' capability dependence. Materials and components based inter-dependence. Government and army specifications dependence.
Tolerance and altruism	Advantages accorded to small local producers and those who manufacture local products	Problem dependent	Little tolerant and altruistic due to the size and the complexity of the organization.	Supporting partners in all kinds of problems.
Inter-organizational relationship nature	Lean management and cooperation through distribution centers. Managing conflict through a movement	Synchronous flow management through excellence centers. Managing conflict through negotiation.	Synchronous flow management across geographical promiscuity. Conflicts depend on the heaviness of problems chronicity.	Partners can work within the production site of the focal firm. Little conflicts. Conflicts are generally solved by financial penalties
Information sharing	Operational and control information is shared. ERP systems are used.	Performance and control information is shared. Open for proposed solutions to improve reliability and quality of service in accordance with regulations. EDI is operated, and ERP (SAP) systems are used.	Real time tracking through EDI and SRM ¹ System.	Depends majorly on the partner (civil or military). Generally use an ERP system (SAP), and EDI.

¹ Service Level Agreement² Original Equipment Manufacturers

Table2: Relational characteristics in Agri-food, sporting, luxury and toy industries.

	Case 5: Agri-food	Case 6: Sporting	Case 7: Luxury	Case 8: Toy
Power and satisfaction	Expert and legitimate power (supervisor)	Non coercive power based on percentage of market share	Non coercive power based on availability of raw materials.	Expert power of leaders. Capacity based power of producers. Satisfaction is based on volume of orders.
Trust and commitment	Partnership period based trust.	Brand and technical based trust. Suppliers' seniority based commitment and trust.	Network based trust, and quality and lead-time commitment	Cognitive trust based on quality and norms respect. Commitment is based also on quality and lead time.
(Inter)dependence	Dependence of the focal company due to material investments and products (ingredients, machine leasing, transport technology)	Activities and operations depend on the Group orientation.	Perenity and brand based interdependence.	Majorly depends on distributors and retailers. Developing exclusiveness in global market.
Tolerance and altruism	Especially with small producers who wants to convert to fair trade (solidarity).	Establishing poles to guide suppliers and help them produce and develop.	Closeness and consensus based tolerance.	Enlarging the variety of product proposed depending on trust.
Inter-organizational relationship nature	A business cooperative system of management. Little conflict (mainly concerns quality and delivery time)	Collaboration based on research and innovation. Lean operations management approach.	Activities are centralized and collaboration with supplier is close on behalf of reactivity. Conflicts are insignificant.	Coordination through purchase centers and collaboration through relocated offices. Conflicts are rare and resolved by credit notes.
Information sharing	Operational information is shared through ERP ² and tractability systems. WMS ³ and e-marketplaces are also used.	Deployment of CAPM ⁴ , ERP, WMS and extranets for communicating majorly operational information.	All types of information can be shared for satisfying customer.	Mainly sharing operational information, namely orders via EDI.

¹ Supplier Relationship Management

² Enterprise Resource Planning

³ Warehouse Management System

⁴ Computer-Aided Production Management

6: CONCLUSION

The framework presented does not pretend to completeness, most important elements were highlighted to make the supply chain community aware of the importance of the social part when apprehending supply chain issues. More specifically, this framework allows us to go through supply chain relational dynamics by underlining the importance of notions such as power, partner satisfaction, tolerance and altruism, the nature of inter-organizational relationships, trust, commitment, interdependence, but information sharing between supply chain members.

Nevertheless, like all research works, our framework presents a number of limitations. We can cite two main ones. The first is related to the conceptualization of the supply chain relational dynamic. Our conceptualization is quite specific to particular situations; as in some sectors and businesses, this dynamics remains dependent to the economic and technical guidance which governs inter-organizational relations. In these industries, companies integrate our framework as an optional element of decision making, avoiding, consequently, the risk of bias that may arise from the relationship. The second limitation is related to the lack of empirical validation for the proposed conceptual framework. Our reflection is based on previous research on the field, but does not include any development on how these variables will be measured in a supply chain context. This can constitute a perspective for future research.

Information sharing presents one of the responses that permit mitigating the bullwhip effect is between supply chain members. Supply chain dynamics is driven by a set of factors that evolve depending on complex environmental changes. A change in one of these factors downstream the supply chain is inevitably translated by amplified one upstream. Called the Bullwhip effect, Lee et al. (1997) defines it as a phenomenon which “occurs when the demand order variabilities in the supply chain are amplified as they moved up the supply chain”. This effect provokes a lot of inefficiencies and unbalances within the supply chain, and happens depending on several causes. Lee et al (1997) highlight four principal ones: demand signal processing or demand forecast updating, order batching, price fluctuation, and rationing and shortage gaming. Actually, most of researchers attribute the bullwhip effect to the irrational behavior of supply chain members. But as we can see in the literature, most of research focuses more on the causes and the consequences of this effect and not much on

factors that can generate these causes. So, this can also present an interesting future research direction.

Finally, we conclude by saying that both technical/economic and social logics have to be included in the cognitive map of a supply chain manager. We can hardly reach performance just by basing our decisions on technical/economic variables and elements. Supply chain performance is conditioned by social relationships that represent in the main its essence, in contrast to logistics, which focuses more on technical factors. Although, this can obviously, be subject to discussion.
