Harsanyi’s aggregation theorem with incomplete preferences

Eric Danan† Thibault Gajdos‡ Jean-Marc Tallon§

January 11, 2014

Abstract

We provide a generalization of Harsanyi (1955)’s aggregation theorem to the case of incomplete preferences at the individual and social level. Individuals and society have possibly incomplete expected utility preferences that are represented by sets of expected utility functions. Under Pareto indifference, social preferences are represented through a set of aggregation rules that are utilitarian in a generalized sense. Strengthening Pareto indifference to Pareto preference provides a refinement of the representation.

Keywords. Incomplete preferences, aggregation, expected multi-utility, utilitarianism.
JEL Classification. D71, D81.

Introduction

Harsanyi (1955)’s aggregation theorem establishes that when individuals and society have expected utility preferences over lotteries, society’s preferences can be represented by a weighted sum of individual utilities as soon as a Pareto indifference condition is satisfied. This celebrated result has become a cornerstone of social choice theory, being a positive aggregation result in a field where impossibility results are the rule, and is viewed by many as a strong argument in favor of utilitarianism.

Harsanyi’s result sparked a rich (and on-going) debate about both its formal structure and substantive content (for an overview see, among others, Sen, 1986; Weymark, 1991; Mongin and d’Aspremont, 1998; Fleurbaey and Mongin, 2012). An important question, in particular, is how robust the result is to more general preference specifications. Most findings on this issue are negative. For instance, moving from (objective) expected utility preferences over lotteries to subjective expected utility preferences over acts results in an impossibility unless all individuals share the same beliefs (Hylland and Zeckhauser, 1979; Hammond, 1981; Seidenfeld, Kadane, and Schervish, 1989; Mongin, 1995; Gilboa, Samet, and Schmeidler, 2004; Chambers and Hayashi, 2006; Keeney and Nau, 2011). This impossibility extends even to the common belief case whenever individual preferences are not necessarily neutral towards ambiguity, as are subjective expected utility preferences (Gajdos, Tallon, and Vergnaud, 2008).

In this note we take issue with the assumption of complete preferences. There are at least two reasons why one may want to allow for incomplete preferences in social choice theory. First, individuals may sometimes be intrinsically indecisive, i.e. unable to rank alternatives (Aumann, 1962; Bewley, 1986; Shapley and Baucells, 1998; Ok, 2002; Dubra, Maccheroni, and Ok, 2004; Evren, 2008; Ok, Ortoleva, and Riella, 2012; Galaabaatar and Karni, 2013; Pivato, 2013). Second, even if individuals all have complete preferences, these preferences may in practice be only partially identified (Manski, 2005, 2011). As we shall see, Paretian aggregation remains possible when individual have incomplete expected utility preferences over lotteries, and still has a utilitarian flavor, although in a generalized sense.

**Statement of the theorem**

Let $X$ be a finite set of outcomes and $P$ denote the set of all probability distributions (lotteries) over $X$. A utility function on $X$ is an element of $\mathbb{R}^X$. We denote by $e \in \mathbb{R}^X$ the constant utility function $x \mapsto e(x) = 1$.

Shapley and Baucells (1998) and Dubra, Maccheroni, and Ok (2004) show that a (weak) preference relation $\succeq$ over $P$ satisfies the reflexivity, transitivity, independence, and continuity axioms if and only if it admits an expected multi-utility representation, i.e. a convex set $U \subseteq \mathbb{R}^X$ such that for all $p, q \in P$,

$$ p \succeq q \Leftrightarrow \left[ \forall u \in U, \sum_{x \in X} p(x)u(x) \geq \sum_{x \in X} q(x)u(x) \right]. $$

These are the standard axioms of the expected utility model (von Neumann and Morgenstern, 1944), except that completeness is weakened to reflexivity (and continuity is slightly strengthened). Thus, given these axioms, $\succeq$ is complete if and only if $U$ can be
taken to be a singleton, i.e. a standard expected utility representation.

Consider a society made of a finite set \( \{1, \ldots, I\} \) of individuals. Each individual \( i = 1, \ldots, I \) is endowed with a (weak) preference relation \( \succcurlyeq_i \) over \( P \) satisfying the above axioms. Society itself is also endowed with a preference relation \( \succcurlyeq_0 \) over \( P \) satisfying these axioms. For all \( i = 0, \ldots, I \), denote by \( \succ_i \) and \( \sim_i \) the asymmetric (strict preference) and symmetric (indifference) parts of \( \succcurlyeq_i \), respectively. Say that the preference profile \( (\succcurlyeq_i)_{i=0}^I \) satisfies Pareto indifference if and only if \( u_i \) \( (\succ_0) \) satisfies Pareto indifference if and only if \( u_0 = \sum_{i=1}^I \alpha_i u_i + \gamma e \) for some \( \theta \in \mathbb{R}^I \) and \( \gamma \in \mathbb{R} \), \( (\succcurlyeq_i)_{i=0}^I \) satisfies Pareto preference if and only if the same holds with \( \theta \in \mathbb{R}^I \).

Thus, in the expected multi-utility setting, Pareto indifference (resp. preference) is necessary and sufficient for the social utility function to consist of a signed utilitarian (resp. utilitarian) aggregation of individual utility functions.

More generally, let us now endow \( \succcurlyeq_i \) with an expected multi-utility representation \( U_i \) for all \( i = 0, \ldots, I \). This allows for preference incompleteness at both the individual and social level. We then obtain the following generalization of Harsanyi’s aggregation theorem. The proof is presented in the Appendix.

**Theorem.** Let \( \succcurlyeq_i \) be a preference relation over \( P \) endowed with an expected multi-utility representation \( U_i \), for all \( i = 0, \ldots, I \).

(a) \( (\succcurlyeq_i)_{i=0}^I \) satisfies Pareto indifference if and only if

\[
U_0 = \left\{ \sum_{i=1}^I \alpha_i u_i - \beta_i v_i + \gamma e : (\alpha, \beta, \gamma, (u_i, v_i)_{i=1}^I) \in \Phi \right\}
\]

for some \((\alpha, \beta)\) and \((u_i, v_i)_{i=1}^I\)-sectionally convex set \( \Phi \subseteq \mathbb{R}^{2I} \times \mathbb{R} \times \prod_{i=1}^I U_i^{2} \).

(b) Assume \( \sum_{i=1}^I \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}} \) is closed. \( (\succcurlyeq_i)_{i=0}^I \) satisfies Pareto preference if and only if

\[
U_0 = \left\{ \sum_{i=1}^I \theta_i u_i + \gamma e : (\theta, \gamma, (u_i)_{i=1}^I) \in \Omega \right\}
\]

for some \( \theta \) and \((u_i)_{i=1}^I\)-sectionally convex set \( \Omega \subseteq \mathbb{R}^I \times \mathbb{R} \times \prod_{i=1}^I U_i \).

Thus, in the expected multi-utility setting, Pareto indifference (resp. preference) is necessary and sufficient for the set of social utility functions to consist of a set of bi-

---

1 See e.g. de Meyer and Mongin (1995) for a rigorous proof in a general setting.
2 A set \( S \subseteq S_1 \times S_2 \) is \( S_1 \)-sectionally convex if \( \{s_2 \in S_2 : (s_1, s_2) \in S\} \) is convex for all \( s_1 \) in \( S_1 \).
3 \( \text{cone}(\cdot) \) denotes conical hull and the sum of two sets is the Minkowski sum.
utilitarian (resp. utilitarian) aggregations of individual utility functions. Bi-utilitarianism aggregates two utility functions $u_i$ and $v_i$ for each individual $i = 1, \ldots, I$, the former with a non-negative weight $\alpha_i$ and the latter with a non-positive weight $-\beta_i$, thereby generalizing signed utilitarianism (which corresponds to the particular case where $u_i = v_i$ for all $i = 1, \ldots, I$). As in Harsanyi’s aggregation theorem, the constants $\gamma$ in the sets $\Phi$ and $\Omega$ do not affect social preferences, so setting them to 0 yields another expected multi-utility representation of $\succeq_0$.

**Comments**

Bi-utilitarianism cannot in general be reduced to signed utilitarianism in part (a) of the theorem, as the following example shows. Let $X = \{x, y, z, w\}$, $I = 2$, $U_0 = \{u_0\}$, $U_1 = \{u_1\}$, and $U_2 = \text{conv}(\{u_2^a, u_2^b\})$, where $u_0, u_1, u_2^a, u_2^b$ are as follows.

$$
\begin{array}{c|cccc}
& u_0 & u_1 & u_2^a & u_2^b \\
\hline
x & 4 & 1 & 1 & -1 \\
y & 1 & 1 & 0 & 0 \\
z & 1 & 0 & 1 & 1 \\
w & 0 & 0 & 0 & 0 \\
\end{array}
$$

Then for all $p, q \in P$, $\forall i = 1, 2, p \sim_i q \iff p = q$, so $(\succeq_i)_{i=0}^2$ trivially satisfies Pareto indifference (consistently with the theorem, we have $u_0 = u_1 + 2u_2^a - u_2^b$). Yet there exists no $(\theta, \gamma, (u_i)_{i=1}^2) \in \mathbb{R}^2 \times \mathbb{R} \times \prod_{i=1}^2 U_i$ such that $u_0 = \sum_{i=1}^2 \theta_i u_i + \gamma e$.

The closedness assumption in part (b) is not innocuous in terms of preference: there are profiles $(\succeq_i)_{i=1}^I$ of individual preference relations satisfying the above axioms for which there exists no profile $(U_i)_{i=1}^I$ of expected multi-utility representations such that $\sum_{i=1}^I \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}}$ is closed. But there are at least two cases where such a $(U_i)_{i=1}^I$ always exists. The first is when $\succeq_i$ satisfies an additional finiteness axiom for all $i = 1, \ldots, I$ (Dubra and Ok, 2002). The second is when $(\succeq_i)_{i=1}^I$ satisfies a minimal agreement condition. When the closedness assumption is not satisfied, $U_0$ can only be shown to be included in the closure of the set in the right hand side of (2) for some $\Omega$. Details are provided in the Appendix.

As in Harsanyi’s aggregation theorem, individual weights are not unique in (1) and (2). Non-uniqueness is more severe when individual preferences are incomplete because the way society selects individual utility functions out of the individual expected multi-utility representations is itself not unique. That is to say, even if $U_i$ is fixed for all $i = 1, \ldots, I$ and the minimal agreement condition holds, it may be the case that $\sum_{i=1}^I \theta_i u_i + \gamma e = $
\[ \sum_{i=1}^{I} \theta_i'w_i + \gamma'e \text{ for some } (\theta, \gamma, (u_i)_{i=1}^{I}) \neq (\theta', \gamma', (u_i')_{i=1}^{I}) \in \mathbb{R}_+ I \times \mathbb{R} \times \prod_{i=1}^{I} U_i \text{ in (2), and similarly in (1).} \]

The theorem can be extended to an infinite set \( I \) of individuals, with the sums in the right-hand sides of (1) and (2) remaining finite. To this end it suffices to apply the current theorem to an artificial society made of a single individual whose preferences are endowed with the expected multi-utility representation \( U = \text{conv}(\bigcup_{i \in I} U_i) \), assuming \( \text{cone}(U) + \{\gamma e\}_{\gamma \in \mathbb{R}} \) is closed for part (b). This provides a generalization of Zhou (1997)’s aggregation theorem to incomplete preferences (in the case where \( X \) is finite).

Social preferences can be more complete than individual preferences and, in particular, \( \succeq_0 \) can be complete even though \( \succ_i \) is incomplete for all \( i = 1, \ldots, I \). In this case, endowing \( \succeq_0 \) with an expected utility representation \( u_0 \), (1) reduces to \( u_0 = \sum_{i=1}^{I} \alpha_i u_i - \beta_i v_i + \gamma e \) for some \( (\alpha, \beta, \gamma, (u_i, v_i)_{i=1}^{I}) \in \mathbb{R}_+ I \times \mathbb{R} \times \prod_{i=1}^{I} U_i^2 \), and (2) to \( u_0 = \sum_{i=1}^{I} \theta_i u_i + \gamma e \) for some \( (\theta, \gamma, (u_i)_{i=1}^{I}) \in \mathbb{R}_+ I \times \mathbb{R} \times \prod_{i=1}^{I} U_i \). On the other hand, social preferences can also be less complete than individual preferences (in the extreme, the social preference relation can reduce to the Pareto-indifference or Pareto-preference relation) and, in particular, \( \succeq_0 \) can be incomplete even though \( \succ_i \) is complete for all \( i = 1, \ldots, I \). In this case, endowing \( \succeq_i \) with an expected utility representation \( u_i \) for all \( i = 1, \ldots, I \), (1) reduces to \( U_0 = \{\sum_{i=1}^{I} \theta_i u_i + \gamma e : (\theta, \gamma) \in \Lambda\} \) for some convex set \( \Lambda \subseteq \mathbb{R}_+ I \times \mathbb{R} \), and (2) to the same with \( \Lambda \subseteq \mathbb{R}_+ I \times \mathbb{R} \).

These two particular cases (complete social preferences with incomplete individual preferences or the other way around) have in common that \( \Phi = \Psi \times W \) for some convex sets \( \Psi \subseteq \mathbb{R}_+ I \times \mathbb{R} \) and \( W \subseteq \prod_{i=1}^{I} U_i^2 \) in (1), and \( \Omega = \Lambda \times V \) for some convex sets \( \Lambda \subseteq \mathbb{R}_+ I \times \mathbb{R} \) and \( V \subseteq \prod_{i=1}^{I} U_i \) in (2). Such a separation between weights and utilities is not always possible. This can be shown from the example above if we now let \( U_0 = \text{conv}(\{u^a_0, u^b_0\}) \), where \( u^a_0 = \frac{3}{4} u_1 + \frac{1}{4} u_2 \) and \( u^b_0 = \frac{1}{4} u_1 + \frac{3}{4} u_2 \). Then \( (\succeq_i)_{i=0}^{I} \) clearly satisfies Pareto preference, yet any \( \Omega \) satisfying (2) contains both \( (\frac{1}{2}, \frac{1}{2}), 0, (u_1, u^a_2) \) and \( ((\frac{1}{4}, \frac{3}{4}), 0, (u_1, u^b_2)) \) but neither \( (\frac{3}{4}, \frac{1}{4}), 0, (u_1, u^2_2) \) nor \( (\frac{1}{4}, \frac{3}{4}), 0, (u_1, u^2_2) \).

Seeking a general characterization, in terms of the preference profile \( (\succ_i)_{i=0}^{I} \), of the possibility of separating weights and utilities in the above sense does not seem a promising avenue of research. Such a separation can be obtained in a multi-profile setting, by means of an additional independence of irrelevant alternatives condition linking distinct profiles \( (U_i)_{i=0}^{I} \) with one another (Danan, Gajdos, and Tallon, 2013). This latter principle, however, also implies that \( W = \prod_{i=1}^{I} U_i^2 \) in (1) and \( V = \prod_{i=1}^{I} U_i \) in (2). It is an open problem to find weaker conditions allowing society to make a selection within the individual sets of utility functions (thereby reducing social incompleteness) while retaining the separation between weights and utilities.
Appendix

On expected multi-utility representations

The following lemma gathers useful properties of expected multi-utility representations. For a proof see Shapley and Baucells (1998, pp. 6–11) or Dubra, Maccheroni, and Ok (2004, pp. 128–131).

Lemma. A preference relation $\succeq$ over $P$ admits an expected multi-utility representation if and only if there exists a closed and convex cone $K \subseteq \mathbb{R}^X$, $K \perp \{\gamma e\}_{\gamma \in \mathbb{R}}$, such that for all $p, q \in P$, $p \succeq q \iff p - q \in K$. Moreover, $K$ is unique, and a convex set $U \subseteq \mathbb{R}^X$ is an expected multi-utility representation of $\succeq$ if and only if $\text{cl} (\text{cone}(U) + \{\gamma e\}_{\gamma \in \mathbb{R}}) = K^*$.

Proof of the theorem

The “if” statements of both parts of the theorem are obvious. We only prove the “only if” statements.

We start with part (b), so assume $\sum_{i=1}^I \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}}$ is closed and $(\succeq_i)_{i=0}^I$ satisfies Pareto preference. It is sufficient to show that for all $u_0 \in U_0$, there exist $\theta \in \mathbb{R}_{+}^I$, $\gamma \in \mathbb{R}$, and $u_i \in U_i$ for all $i = 1, \ldots, I$ such that $u_0 = \sum_{i=1}^I \theta_i u_i + \gamma e$. Indeed, if this claim is correct then the set $\Omega = \left\{ (\theta, \gamma, (u_i)_{i=1}^I) \in \mathbb{R}_{+}^I \times \mathbb{R} \times \prod_{i=1}^I U_i : \sum_{i=1}^I \theta_i u_i + \gamma e \in U_0 \right\}$ satisfies (2) by construction and is $\theta$- and $(u_i)_{i=1}^I$-sectionally convex since $U_0$ is convex.

To prove the claim, let $K_i$ be the closed and convex cone corresponding to $\succeq_i$ in the lemma above, for all $i = 0, \ldots, I$. We then have $\cap_{i=1}^I K_i \subseteq K_0$ by Pareto preference and, hence, $K_0^* \subseteq (\cap_{i=1}^I K_i)^* = \text{cl} (\sum_{i=1}^I K_i^*)$ (Rockafellar, 1970, Corollary 16.4.2). Moreover, again by the lemma above, $K_i^* = \text{cl}(\text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}})$ for all $i = 0, \ldots, I$. Hence

\[
U_0 \subseteq \text{cl} (\text{cone}(U_0) + \{\gamma e\}_{\gamma \in \mathbb{R}}) = K_0^* \subseteq \text{cl} \left( \sum_{i=1}^I K_i^* \right)
\]

\[
\subseteq \text{cl} \left( \sum_{i=1}^I \text{cl} (\text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}}) \right)
\]

\[
= \text{cl} \left( \sum_{i=1}^I (\text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}}) \right)
\]

\[
= \text{cl} \left( \sum_{i=1}^I \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}} \right)
\]

---

$\perp$ denotes orthogonality, $\text{cl}(\cdot)$ denotes closure, and $K^*$ denotes the dual cone of $K$, i.e. $K^* = \{ u \in \mathbb{R}^X : \forall k \in K, \sum_{x \in X} k(x)u(x) \geq 0 \}$. 

6
where the last equality follows from the assumption that $\sum_{i=1}^{I} \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}}$ is closed. Hence for all $u_0 \in U_0$, there exist $\gamma \in \mathbb{R}$ and $u'_i \in \text{cone}(U_i)$ for all $i = 1, \ldots, I$ such that $u_0 = \sum_{i=1}^{I} u'_i + \gamma e$. Moreover, for all $i = 1, \ldots, I$, since $U_i$ is convex we also have $u'_i = \theta_i u_i$ for some $\theta_i \in \mathbb{R}_+$ and $u_i \in U_i$ and, hence, $u_0 = \sum_{i=1}^{I} \theta_i u_i + \gamma e$.

Now for part (a), assume $(\succsim_i)_{i=0}^{I}$ satisfies Pareto indifference. As in part (b) it is sufficient to show that for all $u_0 \in U_0$, there exist $\alpha, \beta \in \mathbb{R}_+^I$, $\gamma \in \mathbb{R}$, and $u_i, v_i \in U_i$ for all $i = 1, \ldots, I$ such that $u_0 = \sum_{i=1}^{I} \alpha_i u_i - \beta_i v_i + \gamma e$. To prove this, define the preference relation $\succsim'_i$ over $P$ by $p \succsim'_i q \Leftrightarrow p \sim_i q$, for all $i = 1, \ldots, I$. We then have $p \succsim'_i q \Leftrightarrow p-q \in K_i \cap (-K_i)$, and $(\succsim_0, \succsim'_i)_{i=1}^{I}$ obviously satisfies Pareto preference, so by the same argument as in the proof of part (b) we obtain $K^*_0 \subseteq \text{cl}(\sum_{i=1}^{I} (K_i \cap (-K_i))^*) = \text{cl}(\sum_{i=1}^{I} \text{cl}(K_i^* - K_i^*))$ (Rockafellar, 1970, Corollary 16.4.2). Hence

$$U_0 \subseteq \text{cl}(\text{cone}(U_0) + \{\gamma e\}_{\gamma \in \mathbb{R}}) = K^*_0 = \text{cl} \left( \sum_{i=1}^{I} (K_i^* - K_i^*) \right)$$

$$\subseteq \text{cl} \left( \sum_{i=1}^{I} (\text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}}) - \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}} \right)$$

$$= \text{cl} \left( \sum_{i=1}^{I} (\text{cone}(U_i) - \text{cone}(U_i)) + \{\gamma e\}_{\gamma \in \mathbb{R}} \right)$$

$$= \text{cl} \left( \sum_{i=1}^{I} (\text{cone}(U_i) - \text{cone}(U_i)) + \{\gamma e\}_{\gamma \in \mathbb{R}} \right)$$

$$= \sum_{i=1}^{I} \text{cone}(U_i) - \sum_{i=1}^{I} \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}}$$

where the before-last equality follows from the fact that $\text{cone}(U_i) - \text{cone}(U_i)$ and $\{\gamma e\}_{\gamma \in \mathbb{R}}$ are subspaces of $\mathbb{R}^X$. Hence for all $u_0 \in U_0$, there exist $\gamma \in \mathbb{R}$ and $u'_i, v'_i \in \text{cone}(U_i)$ for all $i = 1, \ldots, I$ such that $u_0 = \sum_{i=1}^{I} u'_i - v'_i + \gamma e$. Moreover, for all $i = 1, \ldots, I$, since $U_i$ is convex we also have $u'_i = \alpha_i u_i$ and $v'_i = \beta_i v_i$ for some $\alpha_i, \beta_i \in \mathbb{R}_+$ and $u_i, v_i \in U_i$ and, hence, $u_0 = \sum_{i=1}^{I} \alpha_i u_i - \beta_i v_i + \gamma e$.

**On the closedness assumption in part (b) of the theorem**

As can be seen from the proof of part (b), the closedness assumption ensures that each social utility function can be expressed as a non-negative linear combination of some indi-
vidual utility functions (plus a constant function). Without this assumption, each social utility function can only be expressed as the limit of a sequence of such combinations.

For an example in which the assumption is not satisfied and (2) does not hold for any Ω, let \( X = \{x, y, z, w\}, \) \( I = 2, \) \( U_0 = \{u_0\}, \) \( U_1 = \{u_1\}, \) and \( U_2 = \{u_2(s, t) : s, t \in \mathbb{R}, s^2 + t^2 \leq 1\}, \) where \( u_0, u_1, u_2(s, t) \) are as follows.

<table>
<thead>
<tr>
<th></th>
<th>( u_0 )</th>
<th>( u_1 )</th>
<th>( u_2(s, t) )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x )</td>
<td>1</td>
<td>-1</td>
<td>1</td>
</tr>
<tr>
<td>( y )</td>
<td>-1</td>
<td>1</td>
<td>( s )</td>
</tr>
<tr>
<td>( z )</td>
<td>1</td>
<td>0</td>
<td>( t )</td>
</tr>
<tr>
<td>( w )</td>
<td>-1</td>
<td>0</td>
<td>(-1 - s - t)</td>
</tr>
</tbody>
</table>

Then \( \sum_{i=1}^{2} \text{cone}(U_i) = \{u \in \mathbb{R}^X : u(x) + u(y) \geq 0, u(z) = 0 \text{ or } u(x) + u(y) > 0, u(x) + u(y) + u(z) + u(w) = 0\} \) and, hence, \( \sum_{i=1}^{2} \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}} = \{u \in \mathbb{R}^X : u(x) + u(y) \geq u(z) + u(w), 3u(z) = u(x) + u(y) + u(w) \text{ or } u(x) + u(y) > u(z) + u(w)\} \). This latter set is not closed, and indeed \( u_0 \) does not belong to it but belongs to its closure. Hence \( u_0 \) cannot be expressed as a non-negative linear combination of \( u_1 \) and some \( u_2(s, t) \in U_2 \) even though \( (\succeq_i)_{i=0}^{2} \) satisfies Pareto preference. The same conclusion would be reached with any other expected multi-utility representation of \( \succeq_i \) for all \( i = 0, 1, 2 \).

A sufficient condition for the existence of a profile \( (U_i)_{i=1}^{I} \) satisfying the closedness assumption is that \( \sum_{i=1}^{I} K_i^* \) be closed, where \( K_i \) is the closed and convex cone corresponding to \( \succeq_i \) in the lemma above (one can then take \( U_i = K_i^* \), for instance). There are at least two cases where this sufficient condition is always satisfied.

The first case is when each \( K_i \) is polyhedral (Rockafellar, 1970, Corollary 19.2.2, Corollary 19.3.2). This can be characterized by a finiteness axiom on \( \succeq_i \) (Dubra and Ok, 2002). Note that no closedness assumption is needed in part (a) because \( \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}} \) is replaced with \( \text{cone}(U_i) - \text{cone}(U_i) + \{\gamma e\}_{\gamma \in \mathbb{R}} \), which is a subspace of \( \mathbb{R}^X \) and, hence, falls into this case.

The second case is when all \( K_i \)'s have a common point in their relative interiors (Rockafellar, 1970, Corollary 16.4.2). This can be characterized by the following minimal agreement condition: there exist \( p, q \in P \) such that \( p \succeq_i q \) for all \( i \in I \), where \( p \succeq_i q \) is defined by for all \( q_i \in P \) such that \( p \succeq_i q_i \), there exist \( q_i' \in P \) and \( \lambda_i \in (0, 1) \) such that \( p \succeq_i q_i' \) and \( q = \lambda_i q_i + (1 - \lambda_i) q_i' \). Note that if all \( \succeq_i \)'s are complete then this condition boils down to the usual minimal agreement condition, where \( p \succeq_i q \) is replaced with \( p \succ_i q \).

---

7In this case an alternative proof of the theorem consists in considering each extreme point of each individual’s expected multi-utility representation as an expected utility representation of an artificial individual with complete preferences and applying Harsanyi’s aggregation theorem to the artificial society.

8This is a slight refinement, when preferences are incomplete, of the usual minimal agreement condition stating that some lottery is unanimously preferred to some other lottery.
