Abstract
This article sets out a phonemic and tonal analysis of the second author’s native language: the (heretofore undescribed) Naxi dialect spoken in the village of Pianding (Dadong County, Lijiang Municipality, Yunnan). A distributional inventory brings out two pairs of phonemes that are of special interest to Naxi dialectology: (i) two apicalized vowels, /ɿ̟/ and /ɿ̠/, and (ii) two rhotic vowels, /ɚ/ and /ɯ˞/, instead of only one apicalized vowel and one rhotic vowel in Lijiang Old Town (Dayanzhen), the best-described dialect to date. These observations confirm and complement reports from other dialects; information on the lexical distribution of these conservative oppositions enriches the empirical basis for comparative-historical studies within the Naish subgroup of Sino-Tibetan. In the course of the discussion, observations about the Pianding dialect are placed in cross-dialect perspective; this article can thus serve as an introduction to key aspects of Naxi phonemics.

1. Introduction
1.1. Research agenda
This groundwork article sets out a phonemic and tonal analysis of the second author’s native language: the Naxi dialect spoken in the village of Pianding (Dadong County, Lijiang Municipality, Yunnan). A phonemic and tonal analysis based on a distributional inventory constitutes a necessary basis for all aspects of linguistic documentation and research, from the accurate transcription of recorded materials to fine-grained synchronic and diachronic investigations. The present analysis thereby represents a contribution to the long-term endeavour to document and study the dialectal diversity of the Naish subgroup of Sino-Tibetan, which includes Naxi, Na (a.k.a. Mosuo, Narua; see Lidz 2010) and Laze (Huáng Bùfán 2009). The existence of increasingly refined analyses for other language varieties within the Naish subgroup helps focus the discussion on phonemic oppositions of special interest for diachronic studies.¹ In the course of the discussion, observations about Pianding Naxi are placed in cross-dialect perspective; this article can thus serve as an introduction to key aspects of Naxi phonemics.

¹ Reviews of the state of the art in research on Naxi and the Naish subgroup of Sino-Tibetan are proposed by Li (2014) and Michaud, He Limin & Zhong Yaoping (forthcoming).
1.2. Theoretical backdrop

The theoretical backdrop to the present research is classical functional phonology (Martinet 1956:15, 34-47). Specifically, this research follows the approach advocated by Martinet under the name *dynamic synchrony* (Martinet 1990): synchrony and diachrony are kept clearly distinct, but synchronic observations are placed in evolutionary perspective. The ultimate research aim consists in documenting the diachronic evolution from Proto-Naish to each of the present-day dialects, with a degree of detail that approaches the standards of full-fledged sociolinguistic studies. Labov’s *Principles of Linguistic Change* (Labov 1994, 2001, 2010) are a source of inspiration in this long-term endeavour. From a cross-linguistic point of view, case studies that shed light on the conditioning of individual sound changes can ideally contribute to the formulation of *panchronic* laws: language-independent laws of sound change, obtained by induction from a typological survey of precise diachronic events whose analysis brings out their common conditions of appearance (Haudricourt 1940; Mazaudon & Michailovsky 2007). For instance, the observation of nasalized syllables in a Naxi dialect provided the starting-point for an investigation that progressed from comparison within Naish to comparison across Sino-Tibetan and finally to a panchronic study of transfer of nasality between consonantal onset and vowel (Michaud, Jacques & Rankin 2012). Hope of making such discoveries is a major motivation in sifting through dialect data.

1.3. Target language and reference speaker

The language variety under study is spoken in the hamlet of Pianding (片丁), about 70 kilometers to the north-north-east of the city of Lijiang (丽江): see map. [INSERT MAP ON A FULL PAGE, ON THE PAGE THAT FOLLOWS THE ABOVE PASSAGE: “The language variety under study is spoken in the hamlet of Pianding...”.] It is located at a latitude of 27.176 N, and a longitude of 100.389 E. Its current administrative coordinates are: Pianding hamlet, Baishui village, Dadong township, Lijiang Municipality, Yunnan, China. Family genealogies suggest that the hamlet was founded around the year 1860, initially by Naxi families. The current population is about 40 families: thirteen Naxi families coming from two distinct places (presumed to be Baoshan 宝山 and Sanba 三坝), and maintaining distinct ritual habits to this day; and Han Chinese families, who appear to have settled gradually, family after family, since about the year 1900. All Naxi families in the hamlet carry the name He 和, whereas Han Chinese families carry various names: mostly Ma (马) – probably the earliest settlers after the Naxi – but also Wang (王), Zhu (朱), Luo (罗), Yao (姚) and Zhang (张). The Yao and Zhu families, who are later arrivals, maintain a tradition of speaking Chinese, whereas transmission of the Chinese language was lost for the earlier Han Chinese settlers, whose mother tongue is now Naxi. The endonym of the Naxi language is /nɑ˩çi˧/.  

One of the authors of this study (He Likun) is a native speaker of Pianding Naxi. The status of native speaker is often considered to be, in and of itself, indicative of the very best linguistic competence, requiring no further elaboration. In our view, however, it is crucial to provide further indications...
about the speakers. Speech data acquisition is an underestimated challenge (Niebuhr & Michaud 2015); bilingual or multilingual subjects are potentially brilliant collaborators in speech data collection, but one should be aware of potential bias. Speakers with high aural sensitivity, good short-term and working memory, high attentional ability and extensive vocabulary knowledge attune fastest to different accents (Janse & Adank 2012). This is likely to affect their performance as language consultants when living in a language environment other than that of their mother tongue. An individual’s experience of different languages, dialects and sociolects exerts a deep influence on the way s/he speaks. Among other spectacular experimental findings, it has been shown that one minute of exposure is enough for the ear to attune to a foreign accent (Clarke & Garrett 2004). Such phonetic-accommodation effects are reflected in amplified and entrenched forms in the speech of bilingual or multilingual speakers, who are generally “unable to avoid long term interference” (Watson 2002:245). To take an example within the Himalayan linguistic area, a review of a study of the Lhasa Tibetan tone system points out uncertainties due to the main consultant’s life story, and emphasizes that fine points in phonology “would be better established with the typical monolingual (mono-dialectal) native informant” (Mazaudon 1985:94). In view of the importance of this issue, we provide detailed information on the reference consultant.

He Likun was born in 1988 to monolingual parents. Until the age of 12, he lived at the hamlet, where he attended primary school. He then spent three years studying at the Nationalities Middle School (民族中学) in Nankou (南口), a place that has since been promoted to the status of Yulong County seat within Lijiang Municipality (丽江市玉龙县县城). After this, he returned to his home hamlet for one year, then spent three years in the city of Lijiang, completing middle school and then attending high school (from 16 to 19 years old). The first variety of Chinese that he learnt, at middle and high school (after receiving a smattering of it at his home hamlet’s primary school), was a variety of Standard Mandarin spoken by Naxi people, and heavily influenced by Naxi pronunciation. It is locally known as “Naxi Common Speech”: “Na Pu” (纳普) (full form: 纳西普通话 or 纳西族汉语普通话), and is perceived as a substandard variety of Standard Mandarin, this being referred to by contrast as “Biao Pu” 标普, or “Standard Common Speech” (标准普通话). He Likun also has a passive knowledge of Southwestern Mandarin (the dominant Chinese dialect of Yunnan and Sichuan), of which he has never been a fluent speaker. From the ages of 20 to 24, he was an undergraduate at Northern University for Nationalities (北方民族大学) in Ningxia (宁夏), where he learnt Standard Mandarin, largely through self-study, losing fluency in “Na Pu” (纳普) during the process. He acquired some passive knowledge of other Naxi dialects, but never felt social pressure to adopt another pronunciation than that of his home hamlet. He remains a fluent speaker, using Pianding Naxi in oral communication with his relatives. Since 2012, he has been a research student at Yunnan University for Nationalities (云南民族大学). The data reported here were verified with Likun’s father; the only differences that appeared concern the lexicon: Likun had (i) more limited lexical competence, lacking knowledge of some Naxi vocabulary still mastered by his father and
(ii) a less sharp perception of the boundary between recent loanwords (which have a huge impact on
the inventory of syllables, as evidenced by Table 4) and older lexical stock.

2. The consonant system

Like the dialects of Ciending and Eya (see map), the Pianding dialect is more conservative than the
speech of Lijiang Old Town (a.k.a. Dayanzhen dialect), which has the official status of “Standard
Naxi”. But while Pianding Naxi is relatively conservative in terms of its number of phonemes, its
syllabic structure is nonetheless highly eroded. There are no codas or consonant clusters in any
dialect of Naxi, making it, in this respect, typological opposite from not-so-distantly related
Rgyalrong (Jacques 2004:12–82). Syllabic structure only consists of (C)(G)V + Tone, where C is a
consonant, G a glide, and V a vowel or syllabic consonant. The present article successively discusses
consonants, vowels and tones. An inventory of syllables in simple initial * rhyme table form is
proposed in Table 4 (Section 5).

Consonant phonemes are shown in Table 1.

The presentation below lays emphasis on points of special interest.

2.1. Velars, palatals and alveolopalatals

Pianding Naxi contrasts palatal and alveolopalatal initials, e.g. /dziʰ/ ‘human being; living thing’ vs.
/jiʰ/ ‘shirt’. In view of the current distribution of velar and palatal initials, it appears likely that a
change took place from *k to [c] in front of palatalizing sounds: high, front vowels or rhymes
beginning in a /j/ glide. The structural gap left open by this evolution is in the process of being filled
by onomatopoeic expressions, such as /ki˧ti˧ko˧/ and /kʰiːsi˧kʰo˧so˧/ ‘sound of small animals
scurrying around (outside one’s field of vision)’, so that a synchronic description must acknowledge
phonemic velars, palatals, and alveolopalatals.

This raises the issue of the analysis of syllables such as [cɤ˧] ‘leprosy’ or [cə-] ‘neck’: they are
likely to originate in *kjɤ˧ and *kjə˧, respectively, with subsequent palatalization of the initial; if
one recognizes phonemic /c/, they could be interpreted as /cɤ˧/ and /cə˧/. The same analysis could
then be extended to other rhymes with a palatal onglide, such as /jæ/, interpreting [cʰjæ] as /cʰæ/, for instance.

The inventory in Table 4 (Section 5) is especially useful in handling such issues, as it brings out combinatorial properties of initials and rhymes (the latter consisting of the glide, if any, plus the nucleus). Table 4 reveals that rhymes such as /jæ/ and /jɤ/ are attested in a relatively large number of environments; this lends support to the hypothesis that [cʰæ] is the product of the palatalization of a velar initial by a /jæ/ rhyme. Phonemic interpretation without a palatal on-glide after palatal initials (e.g. interpreting [cʰæ] as /cʰæ/) in effect recognizes the metamorphosis of this syllable, with a transfer of the palatal articulation from the rhyme to the initial. This amounts to postulating a diachronic reinterpretation of /jæ/ as /æ/ in this context (i.e. after an initial which was formerly velar, but has now become palatal).

The second author’s native-speaker intuition on this issue is not clear-cut. The question is whether the rhymes in [jæ] ‘very’ and the first syllable of /jæːkæ˩zɿ/ ‘husband’ are the same or not, i.e. whether phonemic interpretation of the former should be /j + jæ˩/ or /j + æ˩/. These rhymes are transcribed here without a palatal on-glide, indicating that the transfer of palatality to the onset is deemed to be complete, hence /cɤ˧/ for ‘leprosy’ and /jæ˨/ for ‘very’. (A similar solution was adopted for Yongning Na: see Michaud 2008.) This issue is also relevant for other Naxi dialects such as Wenhua, where the structural situation (in terms of the syllable inventory) is the same.

The sound [ɲ] likewise results from the palatalization of earlier *n and *ŋ before high, front vowels (or rhymes beginning with the palatal glide /j/). No sound has yet filled the empty phonetic slots [ɲi], [ɲjæ], [ɲɤ], [ɲy] created by the palatalization process. In view of the recognition of palatal stops as a distinct set of initial consonants, it appears reasonable to extend the same treatment to nasals, granting phonemic status to /ɲ/. This amounts to the hypothesis – testable by psychophonetic methods – that this sound is not currently perceived as an allophone of /ŋ/.

2.2. Allophones of the glottal initial /h/

Mazaudon & Michailovsky (1979) analyze Old Town Naxi glottal, velar and palatal unvoiced fricatives as allophones of a glottal phoneme /h/. This analysis is adopted here for the Pianding dialect. From a phonetic point of view, the realization of /h/ is strongly influenced by the articulation of the following vowel: in the Naxi dialects that we are familiar with, a narrow phonetic notation could be [ɯ̥ɯ] for /hɯ/ [æ̥æ] for /hæ/, [ɑ̥ɑ] for /hɑ/ [ɤ̥ɤ] for /hɤ/ and [o̥o] for /ho/.

Allophonic variation does not appear to reach as far back as the uvular region, pace He and Jiang (1985:7), who posit (for the Old Town dialect) a phonemic velar fricative /x/ that has a uvular allophone [χ] when associated with a /y/, /e/, /æ/, /a/, /o/ or /u/.

In the present state of Pianding Naxi, the analysis as /h/ is extended to the initial of loanwords such as /hwæ˧/ (from huǎng ‘flustered, confused’), but as the pronunciation of Chinese borrowings
becomes closer to the Southwestern Mandarin pronunciation, which seems to have more friction (e.g. [xwæŋ] for huǎng 慌 ‘flustered, confused’), it may eventually result in the introduction of a bona fide [x] sound into the system, which could conceivably gain phonemic status, contrasting with /h/. Chinese loanwords have a huge impact on the inventory of syllables, as set out in detail in Table 4.

2.3. Retroflex allophones of dental consonants
Dental stop consonants /tʰ/, /t/, /d/ and /nd/, nasal /n/, and approximant /l/ have retroflex allophones [ʈʰ], [ʈ], [ɖ], [ɳɖ], [ɭ] and [ɳ] in front of the back vowels /ɯ/, /ɯ˞/, /ɚ/, /u/, as well as before /wæ/, /jɑ/ and /jɤ/. Thus, for instance, [ʈʰwæ], [ʈwæ] and [ɳɖwæ] are analyzed as /tʰwæ/, /twæ/ and /ndwæ/.

The combinatorial properties of the retroflex approximant [ɭ] are discussed further in section 3.3.

2.4. Onset-less syllables
Onset-less syllables receive an empty-onset filler. Front close vowels have a [ʝ] onset: the syllable /i/ is realized as [ʝi], /ʏ/ as [ʝʏ]. Back unrounded close vowels have a [ɣ] onset: /u/ is pronounced [ɣɯ], and /ɤ/ as [ɣɤ]. For the back rounded close vowel /u/, the empty-onset filler sounds like [w]: /u/ is realized as [wu]. For /o/, the empty-onset filler is noticeably weaker (a possible phonetic notation would be [ʱo]); this makes good sense in structural terms: realization as [wo], with a clear [w] onset, could threaten confusion with /wɤ/ or /wu/.

Onset-less syllables constitute a handy transition to the topic of vowels.

3. The vowel system
Leaving aside recent Chinese borrowings, the following vowels are found in Pianding Naxi: /i/, /ɛ/, /u/, /ɪ/, /ɛ̃/, /u̯/, /i/, /æ/, /ɑ/, /ɿ̟/, /ɿ̠/, /ə/ (apicalized rhymes), and /ɜ/ (a neutral vowel). To these must be added rhymes comprising a semi-vowel: /jɛ/, /jɛ̃/, /jɑ/; /wɛ/, /wɑ/, /wə/ and /wɛ/. Readers are referred to Appendix B for examples. All of these rhymes have straightforward counterparts in Old Town, Wenhua and Ciending Naxi, except that (i) Old Town Naxi only has one rhotic rhyme (written /ɚ/): Pianding /ɚ/ and /uə/ both correspond to Old Town /ɜ/, as will be explained below, and (ii) Pianding /ɿ/ and /ɿ/ both correspond to the same rhyme in Old Town Naxi, where it is analyzed as an allophone of /uə/.

In addition to these main rhymes, the Pianding phonological system contains some outliers. The rhyme /we/ is mostly found in Chinese borrowings, such as /kwe˥ ‘expensive, precious’ (from gui 贵), but also in two items of native vocabulary: ‘willow tree’, /ʐweɪə˧/ (compare Ciending /ʐʋ̩˧/ and Wenhua /ʐʷə˞˧/), and /hwe˩ ‘to wrestle’. The semivowel [ɥ] is analyzed as an allophone of /w/, after initials with dental to palatal points of articulation. This analysis requires positing a sequence of glides /jw/ for the Chinese borrowing [jɥe˥] ‘moon’ (from yuè 月): it can be phonemicized as /jwe˧˥/ page 6
(distinct from the /w/-initial syllable /we/, as in /wel/ ‘to surround’ (from wéi 围). The [ŋæ] rhyme has been introduced via recent borrowings from Southwestern Mandarin, e.g. [cŋæ] ‘to contribute’ (from juān 捐), [cʰŋæ] ‘pen, sty’ (from quān 围) and [jŋæ] ‘injustice’ (from yuān 愤). It is phonemicized as /wæ/, hence the transcription of the three preceding examples as /cwæ˧/ ‘to contribute’, /cʰwæ˧/ ‘pen, sty’ and /jwæ/ ‘injustice’ (with the same initial /j/ as in /jwe˧˥/ ‘moon’).

As a preliminary to the discussion of the phonemic and phonotactic properties of the rhymes, Figures 1 and 2 show phonetic data on the Pianding Naxi vowel space. These two figures are based on one token of each vowel, spoken in isolation by He Likun in a recording booth, in syllables with an empty phonological onset.\(^2\) The accuracy of formant frequency estimation was verified by visual inspection on Praat’s spectrographic display during the annotation of these vowels; formant frequencies were then automatically retrieved at 1/3, 1/2 and 2/3 of vowel duration using Cédric Gendrot’s Praat script ANALYSE1 (Gendrot, n.d.). The values represented on the figures show the average of measurements at these three time points. Spectrographic observation suggests that formant movement in the course of the vowel is so limited that one average value for each vowel provides a good approximation of vowel quality. Needless to say, a full-fledged acoustic study of Pianding Naxi vowels would require a much more sophisticated procedure for data collection and processing, in order to arrive at a reasonably speaker-independent view of the system. Figures 1 and 2 nonetheless offer a glimpse of the system’s acoustic outlook. Figure 2 suggests that F3 plays an important role in the Pianding Naxi vowel space: in particular, the two rhotic vowels, /ɚ/ and /ɯ˞/, which are neighbours to the apicalized vowel /ɿ/ in the F1-F2 plot (Figure 1), are far apart from it on the F3 axis (Figure 2). The vowel /ə/ has a slightly lighter tinge than the others to reflect its marginal status.

\(^2\) We plan to make this and other recordings available through the Pangloss Collection, about which see Michailovsky et al. (2014). Naxi materials in the Collection are available from: [http://lacito.vjf.cnrs.fr/pangloss/languages/Naxi_en.htm](http://lacito.vjf.cnrs.fr/pangloss/languages/Naxi_en.htm)
Figure 1. A F2-F1 representation of Pianding Naxi vowels, based on 1 token of each vowel by He Likun.

Figure 2. A F2-F3 representation of Pianding Naxi vowels, based on 1 token of each vowel by He Likun.
3.1. Close front vowels /i/ and /ʏ/

Pianding has a rounded high front vowel, as do the Old Town and Wenhua dialects. This vowel is commonly transcribed as /y/ in Naxi (e.g. Fāng Guóyǔ 方国瑜 & Hé Zhiwǔ 1995; Pinson 2012). In the case of Pianding Naxi, however, this vowel is articulated somewhere between close [y] and close-mid [ø]. This echoes an observation made by He Jiren and Jiang Zhuyi (Hé & Jiāng 1985:10) that “when /y/ combines with a bilabial or laminal-alveolar initial, or with the velar initial /x/, its phonetic realization is ø”.

Accordingly, this vowel is here transcribed as /ʏ/. Note that the same choice was made by the linguist Chang K’un (张琨) in his notation of the speech of Mr. He Cai (和才), a Naxi speaker born in Ludian (鲁甸) L, (Li Lin-ts'an, Chang K’un & Ho Ts’ai 1953:xxiv).

The phonetic realization of /ʏ/ in Pianding is consistent with its position within the phonological system. Whereas, among the non-rounded vowels, close /i/ and mid /e/ contrast with each other, and hence must be phonologically specified as close vs. mid, there is only one rounded front vowel. This vowel can therefore range freely inside the close and close-mid phonetic vowel space. A phonological consequence is that /ʏ/ should not necessarily be viewed as the rounded counterpart of /i/ (or of /e/); rather, the close vs. mid opposition can here be said to be neutralized.

The non-rounded close front vowel in Pianding Naxi is not noticeably different from its counterpart in Old Town or Wenhua, and is transcribed simply as /i/.

3.2. Mid front vowel /e/

The non-rounded mid vowel in Pianding Naxi could be transcribed as either /e/ or /ɛ/, as there is no opposition between a close-mid and open-mid vowel. There is currently no clear standard to refer to when facing a choice between two vowel symbols such as these. In the past, Principles of the International Phonetic Association recommended the use of roman letters: “When a vowel is situated in an area designated by a non-roman letter, it is recommended that the nearest appropriate roman letter be substituted for it in ordinary broad transcriptions if that letter is not needed for any other purpose” (International Phonetic Association 1949:7). However, this was based on considerations of...
typographical convenience which are not so relevant anymore since the advent of Unicode, and phonetic accuracy appears to be a more desirable goal. The issue of the choice of phonetic symbols for this particular vowel is illustrated in previous descriptions of Naxi phonemes. He and Jiang (1985:9) have observed, for dialects of the Lijiang plain, that “when /e/ combines with a bilabial or laminal-alveolar initial, its phonetic realization is [ɛ]”. Elsewhere, the symbol /e/ is used for this vowel, e.g. in a description of Ciending Naxi (Michaud & Xú Jíróng 2012), where realizations are reported to be phonetically close to [e].

As one means of obtaining evidence in favour of either /e/ or /ɛ/ for Pianding Naxi, an informal perception test was conducted, playing the vowel at issue (preceded by a labial stop) to a group of Vietnamese listeners. Vietnamese has four degrees of vowel aperture, contrasting /i/, /ɛ/, /e/ and /a/ (Kirby 2011:384). The majority choice of the listeners was /ɛ/ (ê in Vietnamese orthography) rather than /e/ (orthographic e). This does not constitute overwhelming evidence, however: in the absence of a front/back opposition for the open vowel (there is no /ɑ/ contrasting with /a/), Vietnamese /i/, /ɛ/ and /e/ can hardly be considered typical examples of the ‘cardinal’ front unrounded vowels of the IPA. The next step, which must be deferred until a later publication, would consist in acoustic analysis and modelling. The acoustic theory of speech production (Fant 1960) allows for a representation of acoustico-perceptual characteristics of speech sounds by reference to the resonantial properties of the vocal tract: the F-pattern. Unlike IPA notation, a characterization in terms of an F-pattern is sufficiently detailed to serve as input for speech synthesis, via articulatory modelling (Maeda 1996). Speech sounds can be characterized accurately in terms of a target F-pattern and of the articulatory configuration used to attain this pattern, hence the possibility of proposing a notation to describe the phonemes of individual languages by reference to certain fixed acoustical properties (Vaissière 2007; Vaissière 2011b).

3.3. Back vowels /ɯ/, /u/, /o/ and /ɤ/, and neutral vowel /ə/

Among the back vowels of Pianding Naxi, there are two unrounded vowels with clear phonemic status, and two rounded vowels, which can be considered either to be distinct phonemes or to be

---

5 Original quote: “e 与双唇音和舌尖中音声母相拼时，其实际音值为 ɛ。” The same reservations as above apply here concerning the dialect at issue. In the dialects with which the authors are familiar, including Pianding, this phoneme is also realized as [ɛ] after the glottal initial /h/.
allophones, depending on the analysis chosen. After a lateral approximant, both [o] and [u] are found: [lo˧] ‘work’, [[uɭ] ‘to come (IMPERATIVE)’. Since both the initial and the rhyme differ in these two words, this creates a dilemma for phonemic interpretation: should one interpret the vowels as distinctive, and the coronal vs. retroflex articulation of the initial as conditioned by the vowel? Or conversely, should the vowel difference be analyzed as conditioned by the initial?

These two different analyses have been adopted for two different Naxi dialects, Old Town and Wenhua respectively, where the two morphemes [lo˧] ‘work’ and [ɭu˧] ‘to come (IMPERATIVE)’ are also found. In Old Town Naxi, considered in China as “Standard Naxi” (纳西语标准音), these morphemes are analyzed phonemically as /lo˧/ and /lu˧/ respectively by He and Jiang (Hé & Jiāng 1985:7), who point out the complementary distribution of coronal and retroflex initials. An argument for this analysis in Old Town Naxi is that the vowels /u/ and /o/ are also distinct after velars, witness /kʰu˧/ ‘door’ vs. /kʰo˧/ ‘sound, noise’. The opposition of /u/ and /o/ is diachronically secondary but is becoming well-settled inside the Old Town system, supporting the analysis of retroflexion on initial stops and laterals as being contextually conditioned. Hence the analysis of [[ɭu], [[ɭu], [[ɭv], [[ɭw], [[ɭj], [[ɭe] and [[ɭa] as /lɯ˧/, /lɯˀ, /lɤ, /lʊ, /lɤɤ, /lɤe, /lje/ and /lje/ respectively.

For the Wenhua dialect, on the other hand, /l/ and /ɭ/ are analyzed as distinct phonemes contrasting before /o/, e.g. /lo˩/ ‘inside’ vs. /ɭo˩/ ‘yoke’ (Michaud 2006a:41–42). In Wenhua, the noun [lo˧] ‘work’ is phonemicized as /lo˧/. As for the verb [[ɭu] ‘to come (IMPERATIVE)’, in the absence of an opposition between /ɭ/ and /l/ in front of /u/ (there is no [lu] syllable), its initial constitutes the neutralization of the [l]-vs.-l opposition and could be written as L, to reflect its status as an archiphoneme⁶, hence /Lu˧/. Notation as /lu˧/ is more transparent phonetically, but less informative phonologically.

⁶ Here is how Christopher Court explained the notions of neutralization and archiphoneme in his “expanded translation” of Haudricourt (1961): “One of the concepts of the Prague School which has won least acceptance in English-speaking countries is that of the neutralization of phonemic contrast. In order to illustrate this concept, let us take a case from English. In English we have two different phonemes /p/ and /b/. This is proved by dozens of minimal pairs, such as pit : bit, pat : bat and so on. /p/ is a fortis or strong sound, sometimes, but not always aspirated. /b/ is a lenis or weak sound, sometimes, but not always voiced, but always weaker in its articulation than /p/. However there is one environment, following the phoneme /s/ in the same syllable, in which the phonemes /p/ and /b/ do not contrast: we do not have pairs of words spit : sbit, spat : sbat, and so on. The sound which we spell with a p in the words spit, spat etc., is phonetically something between a /p/ and a /b/, and the exact sound of /p/ or /b/ cannot occur in this environment. We say that the phonemic contrast between /p/ and /b/ is neutralized in this environment, and that the sound which is spelled p in spit, spat and so on, does not represent either the phoneme /p/ or /b/, but the “mother” phoneme, so to speak, of both /p/ and /b/. This “mother” phoneme is called the archiphoneme of the phonemes /p/ and /b/. Let us write it as “P”. Then pit, bit and spit are phonemically /pit/, /bit/ and /sPit/. The actual sound which represents the archiphoneme /P/—phonetically an unaspirated, voiceless stop—is called the phonetic “realization” or “representation” of the archiphoneme. Whenever we find an environment in which two closely related phonemes like /p/ and /b/ cannot both occur, we say that the one sound which can occur
In Pianding, it appears appropriate to recognize /o/ and /u/ as synchronically distinct phonemes, since
/o/ and /u/ also contrast after /h/: /hu˧/ ‘to wait’, /ho˧/ ‘soup’, with only very minor phonetic
differences in the realization of the initial (slightly more friction for /ho˧/). The same phonemic
analysis as in Old Town Naxi is therefore proposed: analyzing ‘work’ as /lo˧/, and ‘to come
(IMPERATIVE)’ as /lu˧/.

For the unrounded back vowels, we adopt the notations /ɯ/ and /ɤ/. The vowel /ɯ/ is identical to He
and Jiang, Fang and He, and other authors’ usage. Its apicalized allophones after coronal and
retroflex fricatives and affricates are dealt with separately below. The vowel /ɤ/ corresponds to He
Jiren and Jiang Zhuyi’s [a]. In fact, their transcription (for Old Town, and also for the various other
dialects that they mention) failed to distinguish between two vowels (see Michaud 2013a): (i) the
back mid unrounded vowel /ɤ/, realized as [ɣɤ] in an onset-less syllable; and (ii) the neutral vowel
/ə/. It is the former that corresponds to Pianding /ɤ/. The latter, on the other hand, always constitutes
a syllable on its own, mostly as the initial syllable within disyllables. It appears in kinship terms
referring to one’s elders, and in various grammatical words (see word list). It harmonizes with the
following syllable’s vowel, and is realized with an initial glottal stop.

In Pianding Naxi, a phonetic study conducted by the second author (unpublished thesis) shows that
the average phonetic realization of the neutral vowel /ə/ is lower than the expected central target: it
has a lower first formant than either the theoretical neutral vowel (for a male speaker: formants from
1 to 3 at 500, 1500 and 2500 Hz, respectively) or the mean of all the full vowels in the system
(Browman & Goldstein 1992; Barry 1992). Realizations of the neutral vowel /ə/ are close to [æ]
before front vowels (/æ/, /ɛ/, /ɨ/, /ɤ/) and to /a/ before /ɑ/, /ɒ/, /ʊ/, /ɤ/, /ɨ/, /ɜ/ and /u/.

### 3.4. Open vowels

Pianding Naxi has two open vowels, corresponding straightforwardly to other Naxi dialects such as
Old Town and Wenhua. Some authors transcribe these as /a/ vs. /æ/ (for instance Hé & Jiāng 1985;
Hé Kāixiáng et al. 1989), others as /ɑ/ vs. /æ/ (Fāng Guóyǔ & Hé Zhīwǔ 1995), still others as /a/ vs.
The use of the symbol /a/ can cause some confusion for linguists who consult data from several sources, hence our decision to transcribe them as /æ/ and /ɑ/, unambiguously bringing out their place within the front vs. back opposition.

3.5. The fricative rhyme /ʋ/  
In Pianding Naxi, as in Ciending Naxi, the fricative rhyme corresponding to the Old Town and Wenhua syllabic consonant /v̩/ is realized with mild friction, much closer to a vowel than to a fricative. Accordingly, it is transcribed here as a labiodental approximant, /ʋ̩/.

Allophonic variation of /ʋ̩/ includes a realization [m] for /mʋ̩/ (e.g. in /mʋ̩zɯ˧/ ‘barley’, realized [mz̍]), except in careful (hyperarticulated) speech, where the realization of this syllable is [mu]. This echoes observations about other Naish languages – for instance, the same state of affairs is found in Yongning Na – and about neighbouring Loloish (Yi/Ngwi) languages. “In various Loloish languages some or all of the nasals occur as syllabics. In most such cases the diachronic source is syllables with a nasal initial and a high vowel; sometimes one dialect has nasal syllabics where others have nasals plus a high vowel. This could be called rhyme-gobbling” (Bradley 1989:150; see also Björverud 1998:8). Interestingly, this phenomenon does not extend to dental and velar nasals: /nʋ̩/ and /ŋʋ̩/ are pronounced as [nʋ̩] and [ŋʋ̩] respectively, retaining an oral realization after the initial nasal.

3.6. Rhotic rhymes  
Pianding Naxi contrasts two rhotic rhymes, transcribed as /ə/ and /ɯ/ in view of the comparatively back and high realization of the latter. These two rhymes correspond neatly to the rhymes /ɛ/ and /ɔ/ in Ciending, to the rhymes /ɔ/ and /ɔʰ/ in Wenhua Naxi, and to the rhymes written as /ʌr/ and /ur/ by the linguist Chang K’un, who contributed the phonetic transcriptions in the dictionary of pictograms edited by Li Lin-ts’an (Li Lin-ts’an, Chang K’un & Ho Ts’ai 1953). The /ɛ/ in /ʌr/ and /ur/ is used to indicate rhotacization, not a coronal trill.

This is a highly interesting conservative feature of Pianding, Ciending and Wenhua: the opposition is lost in Old Town Naxi (“Standard Naxi”), which only has one rhotic rhyme, transcribed as /ə/. All the items in the word list currently being compiled that have either of these two rhymes are presented in Appendix A, because information on the lexical distribution of this opposition in Pianding enriches the empirical basis for comparative-historical studies within Naish.7

While the sound correspondence is regular, the sounds themselves are different in Ciending compared with Pianding, and therefore different transcriptions are used. In Ciending, both vowels are articulated somewhat more to the front than in Pianding; of the two Ciending vowels, that further to the back is transcribed as /ə/, and the more fronted one as /ɛ/. In Pianding, on the other hand, the

7 For instance, inclusion of this opposition would significantly enrich the comparative data sets on Naxi rhotic rhymes assembled by Li (2014).
further back of the two vowels is written /uɭ/, while the more front one is represented by the symbol /ɿ/. Table 2 recapitulates correspondences between four dialects.

3.7. Apicalized rhymes

3.7.1. Phonemic analysis

The Old Town and Wenhua dialects of Naxi have apicalized allophones of /uɭ/ after coronal and retroflex fricatives and affricates: /sɿ/, /zɿ/, /tsʰɿ/, /tsɿ/, /dzɿ/, /ndzɿ/ are realized as [ʂɿ], [ʐɿ], [ʦʰɿ], [ʦɿ], [dzɿ], [ndzɿ], and /swɿ/, /zuɭ/, /tsʰuɭ/, /tsɿ/, /dzɿuɭ/, /ndzɿuɭ/ as [ʂɿ], [ʐɿ], [ʦʰɿ], [ʦɿ], [dzɿ], [ndzɿ] respectively.

The situation in Pianding Naxi is similar after retroflex fricatives and affricates, but more complex after coronal fricatives and affricates. As in Baoshan Naxi (Lí Zīhè 2012), Ciending Naxi (Michaud & Xú Jìróng 2012) and Yongning Na (Michaud, field notes), there are two sets of apicalized rhymes. These could be labelled ‘front-apicalized’ and ‘back-apicalized’ and transcribed as [ɿ] and [ɿ] respectively. Importantly, some words only allow a ‘front-apicalized’ pronunciation, others only allow a ‘back-apicalized’ pronunciation, and still others allow both variants. From a strictly synchronic point of view, then, there are three lexical sets. In view of the complexity of this lexical distribution, it appeared useful to set out all the examples found so far: see Table 3, divided into six parts (3a-f) on the basis of the initial consonant.

Table 3. Instances of non-retroflex apicalized rhymes in Pianding Naxi. Freely alternating forms are separated by a tilde, e.g. ‘ndzɿ˧ ~ ndzɿ˦’.

The distribution of lexical items between the front-apicalized and back-apicalized sets is relatively balanced, revealing that this is a well-established opposition, not a marginal one.

The phonetic realization of apicalized rhymes does not provide any clear hints as to their origin or their phonemic analysis. For instance, the Mandarin syllable written as zi in Pinyin is realized as [tsɿ], and phonemicized as /tsi/; its phonetic realization does not seem significantly different from that of the Naxi syllable written as zee in Naxi Pinyin, and phonemicized as /tsɯ/.

Indications on phonemic analysis are to be drawn from the inventory of syllables found in the language variety under investigation. In the case of Wenhua Naxi, interpretation as /i/ for apical vowels was ruled out by the existence of syllables such as /si/, e.g. /siɿ/ ‘poor, destitute’ (phonetically [siɿ]), contrasting with apicalized [sɿɿ] ‘to know’, which is analyzed as /surɿ/ (likewise in Eya Naxi: Zêng Xiăopéng 2011:20–25). In the case of Pianding, the syllables corresponding to Wenhua fricative plus /i/ have alveolo-palatal initials (e.g. ‘poor’ is /ɕiɿ/), so the range of possible phonemic interpretations for [ɿ] and [ɿ] is especially vast: the two apicalized vowels are in complementary distribution with five other vowels, /ɯ/; /ɤ/; /i/; /ɚ/ and /ɯ˞/. This is a case where several options for phonemic analysis are open. In Ciending, where the situation is similar to Pianding in terms of phonetic realization, native speaker Xu Jirong chose to interpret the ‘front-apicalized’ vowel [ɿ] sound as an allophone of /ɯ/, as in Old Town Naxi and Wenhua Naxi, and the ‘back-apicalized’ vowel sound as an allophone of /ɤ/ – a decision which was respected in joint work on this topic (Michaud & Xu Jirong 2012). The authors of the present paper tried to convince themselves of the advantages of one analysis over the other, but eventually concluded that there was no substantial evidence in favour of either of these solutions. Instead, we choose to grant phonemic status to both /ɿ/ and /ɿ/. This can be criticized as leaving the phoneme inventory with a somewhat overly-phonetic slant. This uneconomical choice has a major advantage, however. It draws attention to a key fact of Naxi phonology: as initials and rhymes become tightly coarticulated within syllables that have an essentially CV structure, the ties between allophones become laxer, and oppositions tend to be between syllables rather than between phonemes. This offers fertile ground for psycholinguistic experiments, to investigate topics such as the degree of perceived proximity between a given sound ([ɿ] or [ɿ]) and the various other sounds of which it could be considered an allophone: /ɯ/, /ɤ/, /i/, /ɚ/ and /ɯ˞/. One of the aims of the present article is to bring out research topics such as this one.
Another option for the phonemic analysis of [ɿ] and [ɿ], chosen in a study of Eya Naxi (Zēng Xiàopéng 2011:20–25), consists in describing one of the two rhymes as tense and the other as lax. This suggestion appears to be based partly on the continuing influence of a suggestion by Yang Huandian that, since all Yi (Loloish, Ngwi) languages have a tense/lax contrast on vowels, Naxi must have one too (Yáng Huàndiǎn 1984). The latter argument loses some of its strength, however, in view of the lack of demonstrated regular correspondences between Naxi and Yi, already pointed out by Bradley (1975). From a phonetic point of view, Yang Huandian’s hypothesis was not confirmed by an electroglottographic analysis of Wenhua Naxi (Michaud 2005:228), which revealed overlapping ranges of open quotient – a measurement that provides an indication on the degree of vocal fold abduction (Henrich et al. 2004) – for the vowels described by Yang as ‘tense’ and ‘lax’. Expert listening and preliminary electroglottographic measurements did not reveal evidence of any salient differences at the laryngeal level for Pianding Naxi either.

Leaving aside the issue of its phonemic interpretation, the opposition of [ɿ] and [ɿ] is of great interest for diachronic research. Knowledge of the lexical distribution of this opposition now allows for improvements over earlier comparative work – to date, essentially Jacques et al. (2011) and Lǐ Zīhè (2013). For instance, ‘to tie, to attach’ (拴) is simply /tsɯ˧/ in the language varieties that were taken into account in earlier reconstruction work (Naxi /tsɯ˧/, Na /tsɯ˧/, Laze /tsɯ˧/), leading to a reconstruction as *tsi (Jacques & Michaud 2011:471). Recognition of the opposition among apicalized vowels will allow for a more fine-grained reconstruction.

3.7.2. Cases of devoicing of apicalized rhymes

The syllable /ʂɯ˩/ is entirely voiceless in some contexts. This phenomenon is conditioned by both phonological and morphological factors. The phonological condition on the devoicing of /ɯ/ after /ʂ/ is that it only occurs when the syllable carries L tone; the morphological condition is that it only happens in final position within words of two syllables or more. For instance, /ʈʂʰwːɑ˨ɑ˧ɭɯ˥ʂɯ˩/ ‘ant’ is realized as [ʈʂʰwːɑ˨ɑ˧ɭɯ˥ʂ̍˩], /le˧bɿ˧˥ʂɯ˩/ ‘carrot’ as [le˧bɿ˧˥], and /ci˥ʂɯ˩/ ‘wasp’ realized as [ci˥ʂ̍˩], whereas /ʂɯ˩/ ‘yellow’ is realized as [ʂʅ˩].

This devoicing process provides a useful test for determining whether a given word is treated as a single lexeme, or as a combination of two. Etymologically, /le˧bɿ˧˥ʂɯ˩/ ‘carrot’ consists of /le˧bɿ˧/ ‘radish’ plus the adjective /ʂɯ˩/ ‘yellow’. But the fact that the final syllable is devoiced strongly suggests that trisyllabic /le˧bɿ˧˥ʂɯ˩/ ‘carrot’ is now treated as a single lexeme.

---

8 The search for correspondences between Naxi/Naish and Yi/Loloish nonetheless continues, witness the recent Ph.D. dissertation of Lǐ Zīhè (Lǐ Zīhè 2013). Note that, while different researchers’ assumptions about language relatedness influences their search for outside comparanda and their interpretation of the correspondences in terms of proto-phonemes, the results of the ‘grassroots’ comparative work which is essential to historical linguistics – establishing correspondences between undoubtedly related dialects – is valid irrespective of the assumptions made about family trees at higher levels.
3.7.3. A marginal syllable: /hĩ/

The syllable /hĩ/ (nasalized throughout) is attested only once in our data, in a phrase describing silly-sounding laughter: /hĩ˨-hĩ˧-be˨˧ zæ˨/, EXPRESSIVE + ADVERBIALIZER + ‘to laugh’, meaning ‘to laugh with silly laughter’. Interestingly, this syllable, which looks onomatopoeic in Pianding, is part of the phonemic inventory of various Naish varieties, including those of Fengke, Yongning, and Muli (Michaud & Jacques 2012). However, the authors are not aware of any contact of Pianding Naxi speakers with speakers from these areas, which could have contributed to (re-)introducing this syllable at the margin of the system. This syllable is not indicated in Table 4, saving an extra line in the table.

4. The tone system

The tone system of Naxi is essentially based on three levels, L(ow), M(id) and H(igh), which are easy to identify, and which are identical across dialects such as Old Town, Wenhua and Pianding. Falling contours never play a distinctive role in the phonology or the morphology; on the other hand, distinctive rising contours are found. A striking asymmetry in Naxi dialects is that LH and MH contours are distinguished at the sentence level but neutralized at the lexical level. In Pianding, as in Wenhua (Michaud 2006b; Michaud & He Xueguang 2007), there are productive processes creating rising contours on low- or mid-tone syllables, as in example (1).

(1) [ dɯ˧-ɲi˧˥ ɟy˧ ]

dɯ˧ ɲi˧˥ ɟy˧
one day only (reduced form of /tɑ˥/) EXISTENTIAL_VERB
‘There is only one day left.’

The resulting contour in (1) is MH; there also exist LH contours, derived from L-tone syllables. In the lexicon, however, there is only one rising tone. Words carrying a rising lexical tone include (i) a few tokens of non-borrowed vocabulary, such as the set of COLLECTIVE pronouns /ŋɑ˧˥/, /nɑ˧˥/, /tʰɑ˧˥/ (from 1st to 3rd person), referring to someone’s extended family (clan), and (ii) numerous Chinese loanwords, such as /lɑ˧˥tsɿ˧˥/ ‘candle’ (làzhú 蜡烛). These items are written here with tone ˧˥ (3 to 5 on the Chao scale). It must be made clear, however, that there is no opposition between LH and MH tones at the lexical level and, as such, ˧˥ is a somewhat arbitrary representation, as either notation would have been acceptable. Some syllables that currently carry a rising tone originate etymologically in a L tone, others in a M tone. For instance, the word ‘carrot’ (already mentioned in 3.6.2), /le˧ bʋ̩˧˥ ʂɯ˩/, consists of /le˧ bɿ˩˧˥/ ‘radish’ plus the adjective /ʂɯ˩/ ‘yellow’, i.e. the rising tone on the syllable /bɿ˧˥/ is the product of the modification of a L tone. The second author’s intuition is that the tone of the second syllable in ‘carrot’ is not phonologically different from that of the second syllable in /bɚ˧ bɚ˧˥/ ‘lovely little piglet’, which clearly originates in a M tone. So we adopt the same
notation for the rising tones in /bə́ˀbə السنوات/ ‘lovely little piglet’ and /lə́ˀbəˀlə̃mu˩/ ‘carrot’, despite the etymological evidence that one derives from a L tone and the other from a M tone.

Interesting evidence comes from a few low-tone words, such as the intensive ‘very’, /jæ˩/, which are habitually realized with a rise, as /jæ˩˧˥/. This habitual rise is due to intonational emphasis via a rising contour (Michaud 2006b). This rise is not always present, thus displaying a synchronic alternation between a L tone and a LH tone. Were the L-tone realization /jæ˩/, currently rare, to disappear entirely, it would be interesting to see whether the LH tone of /jæ˩˧˥/ would change to MH (following the general pattern of neutralization of LH and MH in the lexicon), or whether it would introduce a fifth lexical tone: LH. One factor which reduces the likelihood of the development of an opposition between two rising lexical tones in Pianding Naxi is the current situation of gradual language shift to (Southwestern) Mandarin Chinese, which does not have such an opposition. (On the hybrid properties of the tone system of Naxi – three level tones and one contour –, see Michaud 2013b.)

5. Inventory of syllables

Table 4 provides an inventory of Pianding Naxi syllables, in phonemic notation. The code ‘CH’ indicates that the syllable at issue is only found in Chinese loanwords, and the code ‘O’ that it is found only in onomatopoeic words. Glides are considered as part of the rhyme. All the syllables in Table 4 are exemplified in Appendix B.

This table provides a bird’s-eye view of the entire system. It brings out salient facts, such as (i) the relatively high number of gaps, which calls for a study using the tools of historical linguistics; (ii) the high number of onomatopoeic coinages: onomatopoeic pairings of initials and rhymes into new combinations; and (iii) the huge influence of recent Chinese loanwords, which introduce many new combinations of vowels with semivowels. As an illustration of the tensions within the system introduced by loanwords: among early loanwords, /jɯ˞˧˥/, for ‘drug, chemical’ (in /hojɯ˞˧˥/ ‘gunpowder’, huǒyào 火药), is the only attested example of /j/+ /ɯ˞/ in the system. Adding /jɯ˞/ to Table 4, where semivowels are represented as part of the rhyme, would require the creation of an additional column for the entire table, which would be empty save for the “zero initial” line. For the sake of typographical convenience, /jɯ˞/ is simply left out of the table – a compromise which highlights the need for a distinct study focusing on Chinese loans and their respective degrees of integration within the system. From a diachronic point of view, methods to tease apart the various layers have been successfully applied to languages of the area (see in particular Sagart & Xu Shixuan 2001).

6. Conclusion

After sifting through substantial amounts of Pianding Naxi data (a list of about 3,000 words, and a life story of 1,200 words), the phonemic system of this heretofore unstudied dialect can now be considered to be established with a good degree of certainty. The highlights of this study in terms of contributions to Naxi dialectology consist of the observation of (i) two apicalized vowels, /ɿ̟/ and /ɿ̠/, and (ii) two rhotic vowels, /ɿ/ and /ɯ˞/, compared with only one apicalized vowel and one rhotic vowel in Old Town Naxi, the best-described Naxi dialect to date. Information on the lexical distribution of these oppositions enriches the empirical basis for comparative-historical studies.

Among other perspectives for future work, the strong allophonic variation found in Pianding Naxi would well warrant an experimental phonetic study. After monosyllabicization (an evolution common to many Asian languages; see Brunelle & Pittayaporn 2012; Michaud 2012), phonologically rich monosyllables tend to erode further into syllables made up simply of a consonant, an optional glide, a vowel (or syllabic consonant) and a tone. At this stage in the evolutionary process, as illustrated by Naish languages in general, coarticulation tends to become so strong as to raise issues for phonemic analysis.

Acknowledgments

Many thanks to two anonymous reviewers and to Roselle Dobbs for insightful and constructive criticism. The present study was initiated during a stay of the second author at the International Research Institute MICA (Hanoi, Vietnam) from April to June 2014; we are grateful to Hanoi University of Science and Technology and Yunnan University of Nationalities for making this stay possible. Financial support from Agence Nationale de la Recherche (HimalCo project, ANR-12-CORP-0006, and LabEx EFL, ANR-10-LABX-0083—Investissements d’Avenir) is gratefully acknowledged.
