HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

Linguistic representations of objects make use of external representations, shared between human and non-human animals, whose format is numerical.

Object Representations and Their Relation to Negative Shapes: Implications for Numerical Cognition and Its Apparent Evolution

INTRODUCTION

- Language is a window on **core knowledge** and **active representation**
- **Core knowledge** is mainly perceptual
- **Active representation** involves reasoning on objects

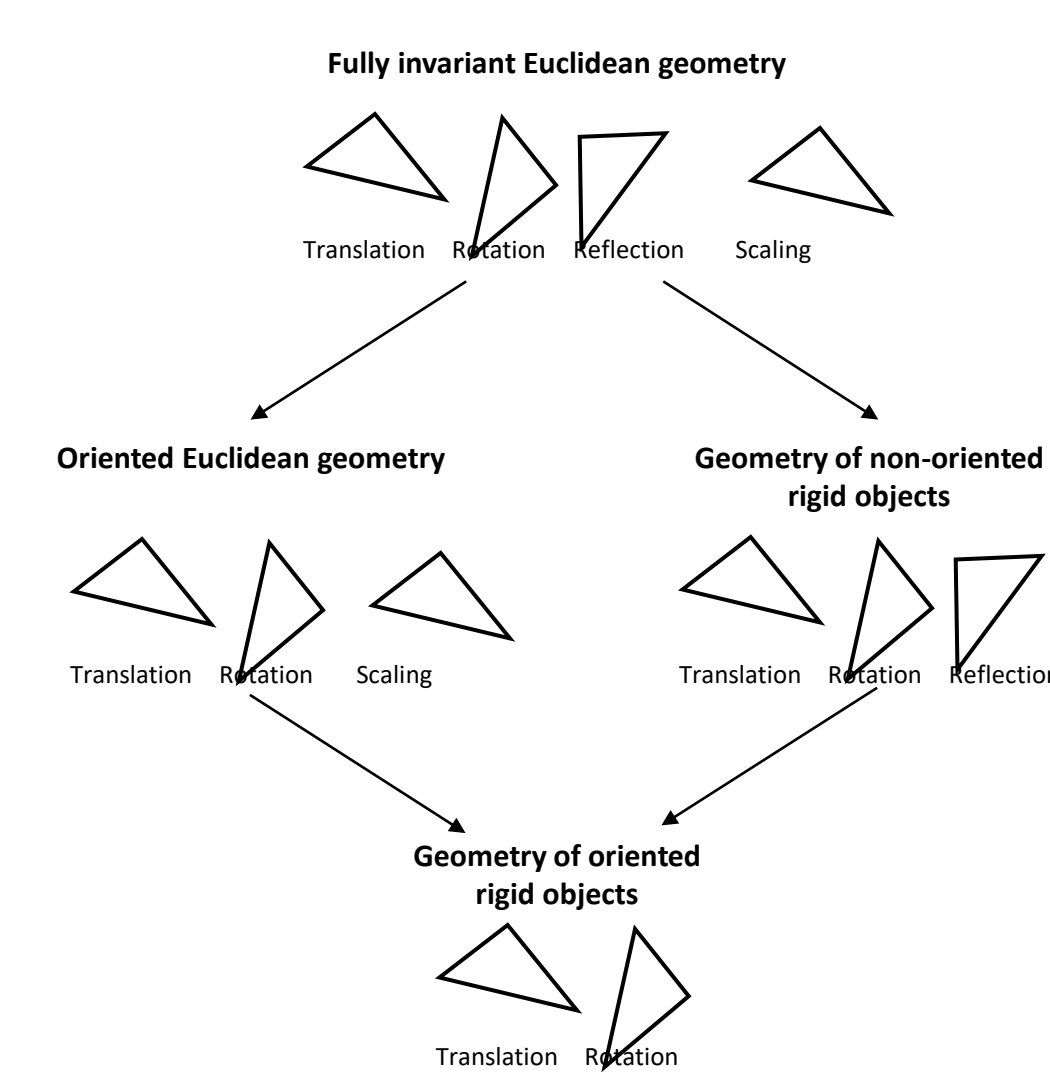

CONTRIBUTION

- In language, **classifiers** express both systems
- One type of classifiers expresses **underspecified shapes** with an independent existence (e.g. an empty round volume that can be filled)
- Another type of classifiers expresses shapes that are **imperfect images** of other objects, that can be more or less complete (e.g. a shadow)
- Both types can be **mapped to quantities**, either by considering the volume of the shape, or the degree of verisimilitude of the image with respect to the original
- Classifiers also provide information on **transformations** of shapes, that is part of active representation

- The two types of classifiers seem to correspond to the **two types of geometries**, identified by (Izard, Pica, and Spelke, submitted)
- One geometry deals with **non-rigid objects**, the other deals with **rigid ones**
- Objects treated by the two geometries are **not divided as simply as we would expect**
- However, **existing division hints at fundamental properties** of core knowledge and active representation

CONCLUSIONS

- **Representations in core knowledge are numerical** (quantitative) in nature
- Language makes use of this representation as the **Language of Thought**
- Following this idea, **language** does not seem to be the product of evolution, but rather the **reorganization of ancient computational systems in the brain**
- Our analysis should be compared against Spelke's leading idea, that language always transforms core knowledge

From (Izard, Pica and Spelke, submitted)

- Example: *-bi* in *bôg-bi* 'wrist' / 'handful'; it expresses an underspecified shape or volume, that is round when it is filled
- Example: *-biog-buk* in *taperadup-biogbuk* 'photocopy'; it express the imperfect image of an object, with its own life (like a shadow)
- Example: liquids are not all part of the same classifier type. *-di* is related to water, and treated as a non-rigid object; *-doy* is related to blood, and interpreted as an imperfect image
- *Water's* shape is defined by the way it falls (geometrical transformation that can be applied to it)
- *Blood's* shape is defined by its viscosity/transparency, interpreted as a degree of verisimilitude
